# Minimizing singularities of generic plane disks with immersed boundaries 

Tobias Ekholm ${ }^{1}$ ) and Ola Larsson

#### Abstract

A cooriented circle immersion into the plane can be extended to a stable map of the disk which is an immersion in a neighborhood of the boundary and with outward normal vector field along the boundary equal to the given coorienting normal vector field. We express the minimal number of fold components of such a stable map as a function of its number of cusps and of the normal degree of its boundary. We also show that this minimum is attained for any cooriented circle immersion of normal degree not equal to one.

## 1. Introduction

We say that a map $F: M \rightarrow \mathbf{R}^{2}$, where $M$ is a compact 2-manifold with boundary, is admissible if it is an immersion in some neighborhood of $\partial M$ and if it has only stable singularities. The singularities of such a map $F$ form a closed codimension one submanifold $\Sigma(F)$ of $M$ and the kernel field of its differential $d F$ is tangent to $\Sigma(F)$ at isolated points called cusps of $F$, see Subsection 2.1. We call the components of $\Sigma(F)$ the fold components of $F$. Let $N(F)$ denote the number of fold components of $F$ and let $C(F)$ denote its number of cusps.

A cooriented circle immersion is an immersion $f: S^{1} \rightarrow \mathbf{R}^{2}$ equipped with a normal vector field $\nu$. The normal degree $W(f)$ of a cooriented immersion $f$ is the degree of the map $\nu: S^{1} \rightarrow S^{1}$, where the source is oriented by the tangent vector field $\tau$ such that the frame $(\nu, d f(\tau))$ represents the positive orientation of $\mathbf{R}^{2}$. Note that this normal degree equals the tangential degree of $f$ or, in other words, its Whitney index [5].

Let $(f, \nu)$ be a cooriented circle immersion. Let $D$ be the unit disk with $\partial D=S^{1}$ and let $n$ be the outward normal vector field of $\partial D$ in $D$. Then there exists a map $F: D \rightarrow \mathbf{R}^{2}$ such that $\left.F\right|_{\partial D}=f$ and such that $d F(n)=\nu$. Note that such a map

[^0]is an immersion in some neighborhood of $\partial D$ and that, after an arbitrarily small deformation vanishing in some neighborhood of $\partial D, F$ is admissible. We call such a map $F$ an admissible map with boundary values ( $f, \nu$ ).

Theorem 1. Let $(f, \nu)$ be a cooriented circle immersion and let $F$ be any admissible map with boundary values $(f, \nu)$. Then $C(F) \neq W(f) \bmod 2$ and the number of folds of $F$ is bounded in the following way.
(a) If $W(f) \leq 0$ then

$$
N(F) \geq \max \left\{\frac{1}{2}(|W(f)|+1-C(F)), 1\right\} .
$$

(b) If $W(f)>1$, or if $W(f)=1$ and $F$ is not an immersion, then

$$
N(F) \geq \max \left\{\frac{1}{2}(W(f)+3-C(F)), 1\right\} .
$$

Moreover, for any fixed $m \geq 0, m \neq W(f) \bmod 2$ there exists an admissible $F$ with boundary values $(f, \nu)$ such that $C(F)=m$ and such that equality holds in the inequality in (a) if $W(f) \leq 0$, and in (b) if $W(f)>0$.

Theorem 1 is proved in Section 3. Similar results for stable maps of closed surfaces were found by Eliashberg [2]. Effective conditions for a circle immersion $f$ with $W(f)=1$ to bound immersed disks were found by Blank, see [4].

## 2. Notation, orientation conventions, and elementary bordisms

In this section the notions and basic techniques used in the proof of Theorem 1 are described.

### 2.1. Singularities of stable maps

Let $F: M \rightarrow \mathbf{R}^{2}$ be a locally stable map of a 2 -manifold to the plane. If $\partial M \neq \emptyset$ then let $F$ be an immersion in some neighborhood of $\partial M$. A theorem of Whitney, see [1], shows that for any point $p \in M$ there are coordinates $x=\left(x_{1}, x_{2}\right)$ around $p \in M$ and $\left(y_{1}, y_{2}\right)$ around $F(p) \in \mathbf{R}^{2}$ such that $F=\left(F_{1}(x), F_{2}(x)\right)$ locally has one of the following forms:

$$
\begin{array}{ll}
\left(F_{1}(x), F_{2}(x)\right)=\left(x_{1}, x_{2}\right), & (p \text { is a regular point }), \\
\left(F_{1}(x), F_{2}(x)\right)=\left(x_{1}^{2}, x_{2}\right), & (p \text { is a fold point }) \\
\left(F_{1}(x), F_{2}(x)\right)=\left(x_{1}^{3}+x_{1} x_{2}, x_{2}\right), & (p \text { is a cusp point })
\end{array}
$$

Figure 1. The characteristic vector at a cusp.
The structure of the singularity set $\Sigma(F)$ of $F$ mentioned in the introduction is a straightforward consequence of this local characterization, see [1]. If $p \in M$ is a cusp point of $F$ then, following [2], we define the characteristic vector at $F(p)$ to be the vector $w$ tangent to $F(\Sigma(F))$ at $F(p)$ which points into the region where the map has local multiplicity 1 . For convenience, we will also call a vector $v$ in $T_{p} M$ such that $d F(v)=w$ a characteristic vector at $p$, see Figure 1.

### 2.2. Punctured disks

For $m \geq 0$, define an $m$-punctured disk $D_{m}$ to be the unit disk $D$ with $m$ open balls, with mutually disjoint closures, removed from its interior: $D_{m}=D \backslash\left(\bigcup_{j=1}^{m} B_{j}\right)$. Then $D_{m}$ is a 2-manifold with boundary. We consider the boundary component $\partial D \subset \partial D_{m}$ of $D_{m}$ as distinguished. We call it the outer boundary component of $D_{m}$ and denote it $\partial D_{m}^{0}$. Other boundary components of $D_{m}$ are called inner, we denote their union $\partial D_{m}^{*}$.

### 2.3. The tree of an admissible map

Let $F: D_{m} \rightarrow \mathbf{R}^{2}$ be an admissible map. The tree $\Gamma(F)$ of $F$ is the directed graph defined as follows.
(V) The vertices of $\Gamma(F)$ are the distinguished boundary component $\partial D_{m}^{0}$ and the fold components of $F$.
(E) There is an edge connecting two vertices $\alpha$ and $\beta$ of $\Gamma(F)$ if there exists a component $E \subset\left(D_{m} \backslash \Sigma(F)\right)$ such that $\alpha \cup \beta \subset \partial E$ and, if $\alpha \neq \partial D_{m}^{0}$ and $\beta \neq \partial D_{m}^{0}$ then $\alpha$ separates $\beta$ from $\partial D_{m}^{0}$. Moreover, we direct an edge with one end on $\partial D_{m}^{0}$ away from $\partial D_{m}^{0}$ and we direct an edge between $\alpha \neq \partial D_{m}^{0}$ and $\beta \neq \partial D_{m}^{0}$ as above from $\alpha$ to $\beta$.

It is easy to verify that $\Gamma(F)$ is a directed tree. We say that a fold $\gamma$ in $\Gamma(F)$ is a level $k$ fold if the shortest path in $\Gamma(F)$ from $\partial D_{m}^{0}$ to $\gamma$ is $k$ edges long.

### 2.4. Orienting immersions and coorienting their boundaries

Let $M$ be an orientable 2-manifold with boundary $\partial M$. Let $F: M \rightarrow \mathbf{R}^{2}$ be an immersion. We orient $M$ by pulling back the standard orientation of $\mathbf{R}^{2}$ and we orient $\partial M$ by the tangent vector $\tau$ such that ( $n, \tau$ ), where $n$ is the outward normal of $\partial M$ in $M$, represents the positive orientation on $M$.

Let $F: D_{m} \rightarrow \mathbf{R}^{2}$ be an admissible map and let $\gamma \subset \Sigma(F)$ be a fold component of $F$. Note that $\gamma$ subdivides $D_{m}$ into two components. We denote these components $M(\gamma)^{+}$and $M(\gamma)^{-}$with notation chosen so that $\partial D_{m}^{0} \subset \partial M(\gamma)^{+}$. Consider a tubular neighborhood $N(\gamma)=\gamma \times I$ of $\gamma$. We write $\partial N=\gamma^{+} \cup \gamma^{-}$, where $\gamma^{ \pm} \subset M(\gamma)^{ \pm}$.

### 2.5. Simple convex double points and standard curves

Let $f: S^{1} \rightarrow \mathbf{R}^{2}$ be a self transverse immersion. Then the multiple points of $f$ are transverse double points. A double point $q$ of $f$ is called innermost if there exists an arc $A_{q} \subset S^{1}$ such that $\left.f\right|_{\operatorname{int}\left(A_{q}\right)}$ is injective and such that $\partial A_{q}=f^{-1}(q)$. It is easy to see that any self transverse circle immersion has an innermost double point.

An innermost double point $q$ together with a specified arc $A_{q}$ as above of a self transverse circle immersion $f$ is called convex if the planar disk $D_{q}$ bounded by $f\left(A_{q}\right)$ satisfies

$$
\frac{\operatorname{area}\left(B \cap D_{q}\right)}{\operatorname{area}(B)}<\frac{1}{2}
$$

for all sufficiently small disks $B$ centered at $q$. Note that the orientation of $S^{1}$ induces an orientation on $f\left(A_{q}\right)$, which is an embedded circle with one corner at $q$. Smoothing the corner we get an oriented circle embedding. We say that $q$ is positive (resp. negative) if the Whitney index of this circle embedding equals 1 (resp. -1).

A convex double point $q$ of $f$ is called simple if $\operatorname{int}\left(A_{q}\right)$ does not contain any double point preimages. A self transverse immersion $f: S^{1} \rightarrow \mathbf{R}^{2}$ is a standard curve if all its double points $q$ are innermost and admit arcs $A_{q}$ so that they are convex and simple. Note that if $f: S^{1} \rightarrow \mathbf{R}^{2}$ is a standard curve with double points $\left\{q_{j}\right\}_{j=1}^{n}$ and if $A_{q_{j}}$ is the specified arc corresponding to $q_{j}$ then $f$ maps $S^{1} \backslash \bigcup_{j=1}^{n} A_{q_{j}}$ to a simple closed planar curve with corners at $q_{1} \ldots . . q_{n}$.

### 2.6. Elementary bordisms of curves

We define three elementary bordisms of curves. A bordism from an immersed curve $f_{0}: S^{1} \rightarrow \mathbf{R}^{2}$ to a an immersed curve $f_{1}: S^{1} \rightarrow \mathbf{R}^{2}$ is an admissible map $F: S^{1} \times$ $[0,1] \rightarrow \mathbf{R}^{2}$ such that $\left.F\right|_{S^{1} \times\{0\}}=f_{0}$ and $\left.F\right|_{S^{1} \times\{1\}}=f_{1}$.
(0) A bordism $F: S^{1} \times I \rightarrow \mathbf{R}^{2}$ of type ( 0 ) introduces two self intersection points $p$ and $q$, and $q$ is a simple convex double point of $f_{1}$. The map $F$ is an immersion, see Figure 2.
$(-)$ A bordism $F: S^{1} \times I \rightarrow \mathbf{R}^{2}$ of type (-) removes a convex double point of $f_{0}$. The map $F$ has one fold component homotopic to $S^{1} \times\left\{\frac{1}{2}\right\}$ with one cusp with characteristic vector pointing towards $S^{1} \times\{0\}$, see Figure 3 .
$(+)$ A bordism $F: S^{1} \times I \rightarrow \mathbf{R}^{2}$ of type ( + ) introduces one convex double point on an embedded arc of $f_{0}$. The map $F$ has one fold component homotopic to $S^{1} \times\left\{\frac{1}{2}\right\}$ with one cusp with characteristic vector pointing towards $S^{1} \times\{1\}$, see Figure 4.

We next describe how the Whitney indices of $f_{0}$ and $f_{1}$, boundaries of an
elementary bordism $F: S^{1} \times I \rightarrow \mathbf{R}^{2}$, are related. Let $n$ be the outward normal vector field of $\partial\left(S^{1} \times I\right)$ in $S^{1} \times I$. Coorient $f_{0}$ by the vector field $d F(n)$ and $f_{1}$ by the vector field $-d F(n)$. A straightforward check gives the following. If $f_{0}$ and $f_{1}$ are related by a bordism of type (0) then

$$
\begin{equation*}
W\left(f_{1}\right)=W\left(f_{0}\right) \tag{1}
\end{equation*}
$$

If $f_{0}$ and $f_{1}$ are related by a bordism with one fold without cusps then

$$
\begin{equation*}
W\left(f_{1}\right)=-W\left(f_{0}\right) \tag{2}
\end{equation*}
$$

If $f_{0}$ and $f_{1}$ are related by a bordism of type ( - ) then

$$
\begin{equation*}
W\left(f_{1}\right)=-W\left(f_{0}\right)+1 \tag{3}
\end{equation*}
$$

If $f_{0}$ and $f_{1}$ are related by a bordism of type ( + ) then

$$
\begin{equation*}
W\left(f_{1}\right)=-W\left(f_{0}\right)-1 \tag{4}
\end{equation*}
$$

Note that the elementary bordisms ( 0 ), ( - ), and ( + ) above can be combined. For example one can construct bordisms which introduces $2 j$ double points via ( 0 ), creates $k$ simple convex double points via ( + ), removes $l$ convex double points via $(-)$, and which has one fold component homotopic to $S^{1} \times\left\{\frac{1}{2}\right\}$ with $k+l$ cusps, $k$ with characteristic vectors pointing towards $S^{1} \times\{1\}$ and $l$ with characteristic vectors pointing towards $S^{1} \times\{0\}$. Moreover, the Whitney indices of the boundary components of such a cobordism satisfy $W\left(f_{1}\right)=-W\left(f_{0}\right)-k+l$.

### 2.7. Cusp elimination

Following [2], we define a surgery operation which decreases the number of cusps of an admissible map $F: M \rightarrow \mathbf{R}^{2}$. Let $F$ be such a map and let $p \neq q$ be points in $\Sigma(F)$ which are cusps. Assume that there exists a smooth arc $a$ in $M$ such that $a \cap \Sigma(F)=\partial a=\{p, q\}$ and assume that the inward normals of $\partial a$ in $a$ are characteristic vectors of $p$ and $q$. Then we define a new map $F^{\prime}: M \rightarrow \mathbf{R}^{2}$ by redefining $F$ in a neighborhood of $a$, see Figure 5. Note that $F^{\prime}$ has two cusps less than $F$ and that $\Sigma\left(F^{\prime}\right)$ is obtained from $\Sigma(F)$ by surgery on $\{p, q\} \approx S^{0}$.

### 2.8. Euler characteristic and index

Let $F: M \rightarrow \mathbf{R}^{2}$ be an immersion of a manifold with boundary. Let $\nu$ be the normalized component of $d F(n)$, where $n$ is the outward normal vector field of $\partial M$

Figure 5. Cusp elimination.
in $M$, which is orthogonal to $\partial M$. Orient $\partial M$ by a tangent vector field $\tau$ such that $(\nu, \tau)$ gives the positive orientation of $\mathbf{R}^{2}$. Then in analogy with the Poincare Hopf theorem, see [3],

$$
\begin{equation*}
\chi(M)=\operatorname{ind}(\nu) \tag{5}
\end{equation*}
$$

where $\chi(M)$ is the Euler characteristic of $M$ and where ind $(\nu)$ is the degree of the $\operatorname{map} \nu: \partial M \rightarrow S^{1}$.

## 3. Proof of Theorem 1

In this section we present a sequence of lemmas which together constitute a proof of Theorem 1.

Lemma 1. Let $F: D \rightarrow \mathbf{R}^{2}$ be an admissible map. Then the Whitney index $W\left(\left.F\right|_{\partial D}\right)$ of $\left.F\right|_{\partial D}$ satisfies $W\left(\left.F\right|_{\partial D}\right) \neq C(F) \bmod 2$.

Proof. To simplify notation, we use the following convention in this proof: if $a \in \mathbf{Z}$ then $\hat{a}=a \bmod 2 \in \mathbf{Z}_{2}$. Consider the tree $\Gamma(F)$ of $F$. For each $k$ let $n(k)$ denote the number of fold curves of level $k$ in $\Gamma(F)$ and let $c(k)$ denote the number of cusps on the fold curves of level $k$. We denote the set of fold curves of level $k$ by $\left\{\gamma_{j}(k)\right\}_{j=1}^{n(k)}$. Define

$$
\widehat{W}^{ \pm}(k)=\sum_{j=1}^{n(k)} \widehat{W}\left(F\left(\gamma_{j}(k)^{ \pm}\right)\right)
$$

(Note that if $f: S^{1} \rightarrow \mathbf{R}^{2}$ is an immersion then $\widehat{W}(f)$ is independent of the orientation on $S^{1}$.) Let $E(k-1, k)$ denote the submanifold of $D$ which is bounded by

$$
\bigcup_{j=1}^{n(k-1)} \gamma_{j}(k-1)^{-} \cup \bigcup_{j=1}^{n(k)} \gamma_{j}(k)^{+}
$$

Note that $\chi(E(k-1, k))=n(k-1)-n(k)$ and that $\left.F\right|_{E(k-1, k)}$ is an immersion.
Let $m$ be the largest integer such that $n(m) \neq 0$. Then, for $\gamma$ a fold curve of level $m, \widehat{W}\left(F\left(\gamma^{-}\right)\right)=1$ since $F\left(\gamma^{-}\right)$bounds an immersed disk. Thus

$$
\widehat{W}^{-}(m)=\hat{n}(m)
$$

It then follows from (2)-(4) that

$$
\widehat{W}^{+}(m)=\hat{n}(m)+\hat{c}(m) .
$$

Assume inductively that

$$
\widehat{W}^{+}(j)=\hat{n}(j)+\sum_{k=j}^{m} \hat{c}(k) .
$$

Equation (5) then implies

$$
\begin{aligned}
\widehat{W}^{-}(j-1) & =\widehat{W}^{+}(j)+\widehat{\chi}(E(j-1, j)) \\
& =\hat{n}(j)+\sum_{k=j}^{m} \hat{c}(k)+\hat{n}(j)+\hat{n}(j-1)=\hat{n}(j-1)+\sum_{k=j}^{m} \hat{c}(k),
\end{aligned}
$$

and another application of (2)-(4) gives

$$
\widehat{W}^{+}(j-1)=\hat{n}(j-1)+\sum_{k=j-1}^{m} \hat{c}(k)
$$

The final stage of this inductive procedure gives

$$
\widehat{W}\left(\left.F\right|_{\partial D}\right)=1+\sum_{k=1}^{m} \hat{c}(k)=1+\widehat{C}(F)
$$

which is the statement of the lemma.
Lemma 2. Let $F: D \rightarrow \mathbf{R}^{2}$ be an admissible map with $C(F)=m$. Then there exists an admissible map $G: D_{m} \rightarrow \mathbf{R}^{2}$ such that $F=G$ in some neighborhood of $\partial D=\partial D_{m}^{o}$, such that $C(G)=0$, and such that for all inner boundary components $\delta \subset \partial D_{m}^{*}, W\left(\left.G\right|_{\delta}\right)=0$.

Proof. Let $q \in D$ be a cusp of $F$. Let $a \subset D$ be a short line segment with one end point at $q$ and directed along a characteristic vector at $q$. If $a$ is sufficiently short then $a \cap \Sigma(F)=q$. Let $B$ be a ball centered at some point in $a$ such that $\left.F\right|_{B}$ is an embedding and such that $B \cap \Sigma(F)=\emptyset$. We define the admissible map $F^{\prime}: D_{1} \rightarrow \mathbf{R}^{2}$

Figure 6. The cylinder map glued in.
by letting it agree with $F$ on $D \backslash B$ and by replacing $\left.F\right|_{B}$ by the map $H$ of the cylinder $S^{1} \times I$ shown in Figure 6. Note that the boundary component of $S^{1} \times I$ where $H$ does not agree with $\left.F\right|_{\partial B}$ is a curve of Whitney index zero. Applying the cusp elimination procedure to the map $F^{\prime}$ we obtain a map $G^{\prime}: D_{1} \rightarrow \mathbf{R}^{2}$ which agrees with $F$ in some neighborhood of $\partial D$. Repeating this construction at each cusp of $F$ gives the desired map $G$.

Lemma 3. Let $F: D_{m} \rightarrow \mathbf{R}^{2}$ be an admissible map which is not an immersion and let $(f, \nu)$ be the cooriented circle immersion $f=\left.F\right|_{\partial D_{m}^{0}}$ and $\nu=d F(n)$, where $n$ is the outward normal vector field of $\partial D_{m}^{0}$. Assume that $W\left(\left.F\right|_{\delta}\right)=0$ for each inner boundary component $\delta \subset \partial D_{m}^{*}$ and that $C(F)=0$. Then the number of fold components of $F$ is bounded in the following way.
(a) If $W(f) \leq 0$ then

$$
N(F) \geq \max \left\{\frac{1}{2}(|W(f)|+1-m), 1\right\}
$$

(b) If $W(f)>0$ then

$$
N(F) \geq \max \left\{\frac{1}{2}(W(f)+3-m), 1\right\} .
$$

Proof. In this proof we use the following notational convention: if $F: D_{m} \rightarrow \mathbf{R}^{2}$ is a map and if $\gamma$ is an oriented curve in $D_{m}$ such that $\left.F\right|_{\gamma}$ is an immersion then we write $W(\gamma)$ for $W\left(\left.F\right|_{\gamma}\right)$, suppressing the map from the notation.

The assumption that $F$ is not an immersion implies $N(F) \geq 1$. The lemma thus follows once we establish

$$
\begin{array}{ll}
|W(f)|+1-m \leq 2 N(F), & \text { if } W(f) \leq 0 \\
|W(f)|+3-m \leq 2 N(F), & \text { if } W(f)>0 \tag{6}
\end{array}
$$

We prove (6) by induction on $N(F)$. Assume that $N(F)=1$ and denote its unique fold component $\gamma$. Note that $\gamma$ subdivides $D_{m}$ into two components $M(\gamma)^{+}$and $M(\gamma)^{-}$, where we use the notation introduced in Subsection 2.4. Furthermore, let $m^{ \pm}$be the number of inner boundary components of $D_{m}$ which are subsets of $\partial M(\gamma)^{ \pm}$. Consider slight shrinkings of $M(\gamma)^{ \pm}$(still denoted by the same symbols) such that $\gamma^{ \pm} \subset \partial M(\gamma)^{ \pm}$. Noting that $\left.F\right|_{M(\gamma)^{ \pm}}$are immersions and using the boundary coorientation conventions in Subsection 2.4, we compute, using (5) and the assumption on vanishing Whitney indices for inner boundary components,

$$
W\left(\partial D_{m}^{0}\right)+W\left(\gamma^{+}\right)=\chi\left(M(\gamma)^{+}\right)=-m^{+}
$$

and

$$
W\left(\gamma^{-}\right)=\chi\left(M(\gamma)^{-}\right)=1-m^{-}
$$

Since $F$ has no cusps, (2) implies

$$
W\left(\gamma^{+}\right)=W\left(\gamma^{-}\right)
$$

(Note that the orientation of $\gamma^{+}$in the present setup differs from the corresponding orientation in Subsection 2.6.) Thus,

$$
W\left(\partial D_{m}^{0}\right)=m^{-}-\left(m^{+}+1\right)
$$

Now, if $W\left(\partial D_{m}^{0}\right) \leq 0$ then

$$
\left|W\left(\partial D_{m}^{0}\right)\right|+1-m=2-2 m^{-} \leq 2
$$

and if $W\left(\partial D_{m}^{0}\right)>0$ then

$$
\left|W\left(\partial D_{m}^{0}\right)\right|+3-m=2-2 m^{+} \leq 2
$$

This establishes (6) for $N(F)=1$.
Let $F: D_{m} \rightarrow \mathbf{R}^{2}$ be a map with $N(F)=N$ and assume that (6) holds for all admissible maps $G$ : $D_{r} \rightarrow \mathbf{R}^{2}$ with $N(G)<N$ (for all $r$ ). Consider the component $E_{0}$ of $D_{m} \backslash \Sigma(F)$ such that $\partial E_{0} \backslash \partial D_{m}^{*}$ consists of the outer boundary component $\partial D_{m}^{0}$ and level one folds. Let $\left\{\gamma_{j}\right\}_{j=1}^{n(1)}$ be the set of level one folds of $F$ and let $m_{0}$ be the number of inner boundary components of $D_{m}$ which are subsets of $\partial E_{0}$. By (5) we have

$$
W\left(\partial D_{m}^{0}\right)+\sum_{j=1}^{n(1)} W\left(\gamma_{j}^{+}\right)=\chi\left(E_{0}\right)=1-n(1)-m_{0}
$$

Since $F$ has no cusps, (2) implies that

$$
W\left(\gamma_{j}^{+}\right)=W\left(\gamma_{j}^{-}\right)
$$

Thus,

$$
\begin{equation*}
W\left(\partial D_{m}^{0}\right)=-\sum_{j=1}^{n(1)}\left(W\left(\gamma_{j}^{-}\right)+1\right)-\left(m_{0}-1\right) \tag{7}
\end{equation*}
$$

which implies

$$
\begin{equation*}
\left|W\left(\partial D_{m}^{0}\right)\right| \leq \sum_{j=1}^{n(1)}\left(\left|W\left(\gamma_{j}^{-}\right)\right|+1\right)+\left|m_{0}-1\right| \tag{8}
\end{equation*}
$$

Note that $M\left(\gamma_{j}\right)^{-}$is a punctured disk with outer boundary $\gamma_{j}^{-}$. Let $m_{j}$ be the number of inner boundary components of $M\left(\gamma_{j}\right)^{-}$. Moreover, $F_{j}=\left.F\right|_{M\left(\gamma_{j}^{-}\right)}$is an admissible map. Let $N_{j}=N\left(F_{j}\right)$ and note that $N_{j}<N$. Let $X \subset\{1, \ldots, n(1)\}$ be the subset of $j$ such that $N_{j}=0$ and $m_{j}=0$, let $Y \subset\{1, \ldots, n(1)\}$ be the subset of $j$ such that $N_{j}=0$ and $m_{j}>0$ and let $Z=\{1, \ldots, n(1)\} \backslash(X \cup Y)$. For $j \in X \cup Y, F_{j}$ is an immersion and (5) gives

$$
\begin{equation*}
W\left(\gamma_{j}^{-}\right)=1-m_{j} \tag{9}
\end{equation*}
$$

For $r \in Z$, the inductive assumption gives

$$
\begin{equation*}
\left|W\left(\gamma_{r}^{-}\right)\right|+1 \leq 2 N_{r}+m_{r} \tag{10}
\end{equation*}
$$

Equations (8), (9), and (10) imply (with $|A|$ denoting the number of elements in the set $A$ ),

$$
\begin{aligned}
\left|W\left(\partial D_{m}^{0}\right)\right| & \leq \sum_{j \in X}(1+1)+\sum_{k \in Y}\left(\left(m_{k}-1\right)+1\right)+\sum_{r \in Z}\left(2 N_{r}+m_{r}\right)+\left|m_{0}-1\right| \\
& \leq 2|X|+m+1+\sum_{r \in Z} 2 N_{r}=2(N-|Y|-|Z|)+m+1
\end{aligned}
$$

Thus, if $|Y|+|Z| \geq 2$ then $\left|W\left(\partial D_{m}^{0}\right)\right|+3-m \leq 2 N$, and it remains only to check that (6) holds when $|Y|+|Z|<2$ (and $N>1$ ).

Assume first $|Y|=|Z|=0$. Then $W\left(\gamma_{j}^{-}\right)=1$ for $1 \leq j \leq n(1)$. Equation (7) then implies

$$
W\left(\partial D_{m}^{0}\right)=-2 n(1)-m_{0}+1=-2 N-m+1<0
$$

since $N>1$, and

$$
\left|W\left(\partial D_{m}^{0}\right)\right|+1-m=2 N
$$

Hence (6) holds if $|Y|=|Z|=0$.
Assume secondly that $|Y|=1$ and $|Z|=0$. Choose notation so that $1 \in Y$. Then $W\left(\gamma_{1}^{-}\right)=1-m_{1}$ by (5), and (7) gives

$$
W\left(\partial D_{m}^{0}\right)=-2(n(1)-1)+\left(m_{1}-2\right)+1-m_{0}=m_{1}-m_{0}+1-2 N .
$$

Therefore, if $W\left(\partial D_{m}^{0}\right)>0$ then

$$
W\left(\partial D_{m}^{0}\right)+3-m=4-2 m_{0}-2 N \leq 2 N
$$

since $N>1$, and if $W\left(\partial D_{m}^{0}\right) \leq 0$ then

$$
\left|W\left(\partial D_{m}^{0}\right)\right|+1-m=2 N-1-2 m_{1} \leq 2 N
$$

Hence (6) holds if $|Y|=1$ and $|Z|=0$.
Assume thirdly that $|Y|=0$ and $|Z|=1$. Choose notation so that $1 \in Z$. Then (7) gives

$$
W\left(\partial D_{m}^{0}\right)=-2(n(1)-1)-\left(W\left(\gamma_{1}^{-}\right)+1\right)-m_{0}+1=2-2 n(1)-W\left(\gamma_{1}^{-}\right)-m_{0}
$$

Suppose first that $W\left(\gamma_{1}^{-}\right)>0$. Then $W\left(\partial D_{m}^{0}\right)<0$ and

$$
\begin{aligned}
\left|W\left(\partial D_{m}^{0}\right)\right|+1-m & =2 n(1)+W\left(\gamma_{1}^{-}\right)+m_{0}-2+1-m \\
& \leq 2 n(1)+\left(2 N_{1}-1+m_{1}\right)+m_{0}-1-m=2 N-2 \leq 2 N
\end{aligned}
$$

where the inductive assumption and $N_{1}>0$ (since $1 \in Z$ ) was used. Hence (6) holds if $W\left(\gamma_{1}^{-}\right)>0$. Suppose secondly that $W\left(\gamma_{1}^{-}\right) \leq 0$. Then

$$
W\left(\partial D_{m}^{0}\right)=2-2 n(1)+\left|W\left(\gamma_{1}^{-}\right)\right|-m_{0}
$$

If $W\left(\partial D_{m}^{0}\right)>0$ then

$$
\begin{aligned}
W\left(\partial D_{m}^{0}\right)+3-m & =5-2 n(1)+\left|W\left(F\left(c_{1}^{-}\right)\right)\right|-m_{0}-m \\
& \leq 5-2 n(1)+\left(2 N_{1}-1+m_{1}\right)-m_{0}-m=4-2 n(1)+2 N_{1}-2 m_{0} \leq 2 N
\end{aligned}
$$

since $n(1) \geq 1$ (and hence $N-N_{1} \geq 1$ ). If, on the other hand, $W\left(\partial D_{m}^{0}\right) \leq 0$ then

$$
\begin{aligned}
\left|W\left(\partial D_{m}^{0}\right)\right|+1-m & =2 n(1)+m_{0}-\left|W\left(\gamma_{1}^{-}\right)\right|-2+1-m \\
& =2 n(1)-2 m_{1}-\left|W\left(\gamma_{1}^{-}\right)\right|-1 \leq 2 N
\end{aligned}
$$

We conclude that (6) holds in the case $|Y|=0$ and $|Z|=1$.
We have thus shown that (6) holds also when $|Y|+|Z|<2$ for $N(F)=N$. This completes the proof of the lemma.

Figure 7. A disk bounded by a figure eight curve. The boundary is dashed and the fold is solid.

Lemma 4. Let $(f, \nu)$ be a cooriented circle immersion with $W(f)=0$. Then there exists an admissible map $F: D \rightarrow \mathbf{R}^{2}$ with boundary values $(f, \nu)$, such that $N(F)=C(F)=1$. Moreover, if $\gamma$ denotes the fold component of such a map then the characteristic vector at the cusp points into $M(\gamma)^{+}$.

Proof. We first note that there exists such a map $F: D \rightarrow \mathbf{R}^{2}$ if $f: S^{1} \rightarrow \mathbf{R}^{2}$ is the figure eight curve with any coorienting vector field, see Figure 7. Note that if $\gamma$ is the fold component of $F$ then the characteristic vector of the cusp of $F$ points into $M(\gamma)^{+}$.

Let $(f, \nu)$ be any cooriented circle immersion with $W(f)=0$. We first transform $f$ to a curve of standard form using a combination of elementary bordisms. In the construction below we use the coorientation convention for the boundary of a bordism described in Subsection 2.6.

First note that $f$ has an innermost double point, see Subsection 2.5. Let $q$ be such a double point and let $A_{q} \subset S^{1}$ be the corresponding arc where $f$ is injective. Fix some arc $B_{q} \subset S^{1}$ such that $B_{q} \cap A_{q}=\emptyset$ and such that there are no double point preimages of $f$ in $B_{q}$. We construct a bordism $F: S^{\mathbf{1}} \times I \rightarrow \mathbf{R}^{2}$ from $f=f_{0}$ to $f_{1}$ which removes $q$ and introduces simple convex double points with preimages in $B_{q}$. Moreover, all fold components $\gamma$ of $F$ have the following property
(P) $\gamma$ is homotopic to $S^{1} \times\left\{\frac{1}{2}\right\}$ and has exactly two cusps with characteristic vectors pointing into different components of $S^{1} \times I-\gamma$.

Assume first that $q$ is a convex positive innermost double point. Then we use a bordism which is a combination of elementary bordisms of types ( - ) and $(+)$ : we shrink the loop $f\left(A_{q}\right)$ into a cusp and we create, through a cusp in $B_{q}$, a small simple convex double point in $B_{q}$. Note that if $f_{1}$ is the resulting cooriented circle immersion then $W\left(f_{1}\right)=0$ by (3) and (4). and that the fold component of $F$ satisfies (P).

Assume secondly that $q$ is a convex negative innermost double point. We use an initial bordism of type (0) along $B_{q}$ which creates double points $p^{\prime}$, and $q^{\prime}$ which

Figure 8. The cylinder map glued in.
is a simple convex positive double point in $B_{q}$. We compose this initial bordism with a bordism as above removing $q^{\prime}$ and introducing another simple convex double point in $B_{q}$. Note that this bordism satisfies (P). Moreover, the coorientation of the resulting $f_{1}$ is opposite to that of $f$ and therefore $q$ is a convex positive double point of $f_{1}$. Also, $p^{\prime}$ is a simple convex double point of $f_{1}$ in $B_{q}$. We now repeat the construction from above removing $q$ and introducing yet another convex double point in $B_{q}$.

Assume thirdly that $q$ is a non-convex positive innermost double point. Then we apply an initial bordism shrinking $f\left(A_{q}\right)$, as shown in Figure 8, creating two small positive convex simple double points. Composing this with a bordism as in the first case we remove one of these double points and introduce one convex double point in $B_{q}$. We finally continue the bordism as indicated in the last picture in Figure 8 and remove the remaining two double points. The resulting bordism has the desired properties.

Assume fourthly that $q$ is a non-convex negative innermost double point then we first reverse the orientation of $f$ as in the second case and then proceed as in the third case. Again the resulting bordism has the desired properties.

Note that for all the bordisms above, the number of double points of $f_{1}$ in the complement of the distinguished arc $B_{q}$ is strictly smaller than the corresponding number of double points for $f=f_{0}$. To continue the construction we consider the immersion $\tilde{f}$ obtained by deleting the small kinks in $B_{q}$ from $f$. Let $q_{1}$ be an innermost double point of $\tilde{f}$. If $B_{q} \cap A_{q_{1}}=\emptyset$ then $q_{1}$ is an innermost double point also of $f$ and the above construction can be continued with $B_{q_{1}} \subset B_{q}$. If $B_{q} \cap A_{q_{1}} \neq \emptyset$ then $B_{q} \subset A_{q_{1}}$. Choose $B_{q_{1}}$ disjoint from $A_{q}$ and use initial bordisms as in the first and second cases above to remove all the simple convex double points from $B_{q}$ at the cost of introducing new convex simple double points in $B_{q_{1}}$. The construction then proceeds as above.

This procedure is iterated until $f$ has no double points except for simple and convex double points with preimages in the distinguished arc. This way we have constructed a bordism $F: S^{\mathbf{1}} \times I \rightarrow \mathbf{R}^{2}$ of the required form. Moreover, $W\left(f_{1}\right)=0$

Figure 9. Removing two convex double points of opposite signs.

Figure 10. Eliminating all cusps but one.
and thus the sum of the signs of all the double points must equal $\pm 1$.
We remove a pair of a negative and a positive double point using a bordism of the following type. Contract the loop of the positive double point and add a new double point on the negative loop, see Figure 9. (This is a combination of elementary bordisms of types ( - ) and ( + ). The resulting curve looks like the result of a (0) elementary bordism with reversed orientation we can thus cancel the two double points. Also this bordism satisfies ( P ). We continue this removal procedure until we reach a curve (ambient) isotopic to the figure eight curve. Thus, there exists a bordism $F: S^{1} \times I \rightarrow \mathbf{R}^{2}$ such that $f_{0}=f$ and $f_{1}$ is a figure eight curve and such that all fold components of $F$ satisfy ( P ). We complete the map of the cylinder to a map of the disk by filling $F\left(S^{1} \times\{0\}\right)$ by the solution for the figure eight curve discussed above.

We have constructed an admissible map $G: D \rightarrow \mathbf{R}^{2}$ such that $\Gamma(G)$ is homeomorphic to an interval with integer endpoints and vertices at the integers between the end points. Moreover there is one characteristic vector pointing in each direction on all fold components except the last (i.e. the innermost) one which has an outwards characteristic vector. Applying cusp cancellation we arrive at the desired $F: D \rightarrow \mathbf{R}^{2}$, see Figure 10 .

Lemma 5. Let $(f, \nu)$ be a cooriented immersion and let $m$ be any integer such that $m \neq W(f) \bmod 2$. Then there exists an admissible map $F: D \rightarrow \mathbf{R}^{2}$ with boundary values $(f, \nu)$ such that $C(F)=m$ and such that
(a) if $W(f) \leq 0$ then

$$
N(F)=\max \left\{\frac{1}{2}(|W(f)|+1-C(F)) .1\right\}
$$

(b) if $W(f)>0$, then

$$
N(F)=\max \left\{\frac{1}{2}(W(f)+3-C(F)), 1\right\} .
$$

Proof. Assume first that $W(f)>0$. Let $m^{\prime}=\max \{m-W(f)-1,0\}$. Note that $m^{\prime}$ is even. Create $W(f)+1+\frac{1}{2} m^{\prime}$ simple convex positive double points using a combination of elementary bordisms of type ( 0 ). Compose this bordism with a bordism that removes all these $W(f)+1+\frac{1}{2} m^{\prime}$ double points and which introduces $1+\frac{1}{2} m^{\prime}$ simple convex double points. (A combination of elementary bordisms of types ( - ) and (+).) If $G: S^{1} \times I \rightarrow \mathbf{R}^{2}$ denotes this bordism ( $g_{0}=f$ ) then $N(G)=1$, $C(G)=W(f)+2+m^{\prime}$, and using the orientation convention in Subsection 2.6,

$$
W\left(g_{1}\right)=-W(f)+\left(W(f)+1+\frac{1}{2} m^{\prime}\right)-\left(1+\frac{1}{2} m^{\prime}\right)=0
$$

Moreover, $W(f)+1+\frac{1}{2} m^{\prime}$ of the cusps have characteristic vectors pointing towards $S^{1} \times\{0\}$ and $1+\frac{1}{2} m^{\prime}$ of them have characteristic vectors pointing towards $S^{1} \times\{1\}$. Since $W\left(g_{1}\right)=0$ we can complete the map of the cylinder to a map of a disk gluing in a map as in Lemma 4. We obtain a map $G: D \rightarrow \mathbf{R}^{2}$ with $N(F)=2$. Since at least one of the cusps on the level one fold component has its characteristic vector pointing towards the level two fold component and the characteristic vector on the level two fold component is outwards we apply cusp elimination and obtain a map $F: D \rightarrow \mathbf{R}^{2}$ with $N(F)=1$ and $C(F)=W(f)+1+m^{\prime}$. If $m^{\prime}>0$ then $W(f)+1+m^{\prime}=$ $m$ and this is the desired map. Assume $m^{\prime}=0$ then $F$ is a map with $N(F)=1$ and $C(F)=W(f)+1$ and all characteristic vectors of the cusps point towards $\partial D$. Applying cusp elimination to $p$ pairs of such vectors we obtain

$$
C(F)=W(f)+1-2 p \quad \text { and } \quad N(F)=1+p
$$

Thus

$$
W(f)+3-C(F)=2(p+1)=2 N(F) .
$$

as desired.
Assume second that $W(f) \leq 0$. Let $m^{\prime}=\max \{m-|W(f)|+1,0\}$. Note that $m^{\prime}$ is even. Create $\frac{1}{2} m^{\prime}$ simple convex positive double points using a combination of
elementary bordisms of type ( 0 ). Compose this bordism with a bordism that removes all these $\frac{1}{2} m^{\prime}$ double points and which introduces $|W(f)|+\frac{1}{2} m^{\prime}$ simple convex double points. (A combination of elementary bordisms of types ( - ) and ( + ).) If $G: S^{1} \times I \rightarrow \mathbf{R}^{2}$ denotes this bordism $\left(g_{0}=f\right)$ then $N(G)=1, C(G)=W(f)+m^{\prime}$, and using the orientation convention in Subsection 2.6.

$$
W\left(g_{1}\right)=-W(f)-\left(|W(f)|+\frac{1}{2} m^{\prime}\right)+\frac{1}{2} m^{\prime}=0 .
$$

Moreover, $\frac{1}{2} m^{\prime}$ of the cusps have characteristic vectors pointing towards $S^{1} \times\{0\}$ and $|W(f)|+\frac{1}{2} m^{\prime}$ of them have characteristic vectors pointing towards $S^{1} \times\{1\}$. Since $W\left(g_{1}\right)=0$ we can complete the map of the cylinder to a map of a disk gluing in a map as in Lemma 4. We obtain a map $G: D \rightarrow \mathbf{R}^{2}$ with $N(F)=2$.

Noting that $|W(f)|=0$ implies $m^{\prime} \geq 2$, we conclude $|W(f)|+\frac{1}{2} m^{\prime}>0$. Thus, at least one of the cusps on the level one fold component has its characteristic vector pointing towards the level two fold component. Since the characteristic vector on the level two fold component is outwards we may apply cusp elimination and obtain a map $F: D \rightarrow \mathbf{R}^{2}$ with $N(F)=1$ and $C(F)=|W(f)|+m^{\prime}-1$. If $m^{\prime}>0$ then $m=$ $|W(f)|+m^{\prime}-1$ and this is the desired map. Assume $m^{\prime}=0$ (and hence $W(f) \neq 0$ ), then $F$ is a map with $N(F)=1$ and $C(F)=|W(f)|-1$ and all characteristic vectors of the cusps point inwards. Applying cusp elimination to $p$ pairs of such vectors we obtain

$$
C(F)=|W(f)|-1-2 p \quad \text { and } \quad N(F)=1+p
$$

Thus

$$
|W(f)|+1-C(F)=2(p+1)=2 N(F)
$$

This completes the proof of the lemma.
Proof of Theorem 1. The first statement is Lemma 1. The estimates in (a) and (b) follow from Lemmas 2 and 3, respectively. The last statement is Lemma 5.
