Abstract. Let $k = \mathbb{F}_q(t)$, with $q$ odd. In this article we introduce “definite” (with respect to the infinite place of $k$) Shimura curves over $k$, and establish Hecke module isomorphisms between their Picard groups and the spaces of Drinfeld type “new” forms of corresponding level. An important application is a function field analogue of Gross formula for the central critical values of Rankin type $L$-series coming from automorphic cusp forms of Drinfeld type.

2000 Mathematics Subject Classification: 11R58 11G18 11F41 11F67
Keywords and Phrases: function field, quaternion algebra, Shimura curve, automorphic form, Hecke operator, special value of $L$-series.

Introduction

We present here a theory of “definite” quaternion algebras over the rational function field $k := \mathbb{F}_q(t)$ with $q$ odd, “definite” means that the place $\infty$ at infinity ramifies for the quaternion algebra in question. Following Gross [8], we first give a geometric translation of Eichler’s arithmetic theory of definite quaternion algebra by introducing the so-called “definite” Shimura curves. The geometry of these curves is simple and easy to manipulate. Basing on Eichler’s trace computation, one is lead (via Jacquet-Langlands) to an explicit Hecke module isomorphism between the Picard groups of definite Shimura curves and spaces of automorphic forms of Drinfeld type over the function field $k$.

Automorphic forms of Drinfeld type are very useful tools for function fields arithmetic (cf. [7], [12] and [17] for more details and applications), which can be viewed as an analogue of classical modular forms of weight 2. To illustrate our approach to quaternion algebras over function field, we give an application to the study of central critical values of certain $L$-series of “Rankin

\footnote{Both authors were supported by National Science Council grant (100)-2119-M002-007. The first author was also supported by the Graduate Students Study Abroad Program of National Science Council.}
type” in the global function field setting. These \( L \)-series include, among others, \( L \)-series coming from elliptic curves over \( k \) with square free conductor supported at even number of places and having split multiplicative reduction at \( \infty \). Having the extensive calculations done in [12], we obtain in particular a function field analogue of Gross formula for the central critical values of these \( L \)-series over “imaginary” quadratic extensions of \( k \) (with respect to \( \infty \)).

The structure of this article is modelled on [8]. Let \( D \) be a “definite” quaternion algebra over \( k \) and let \( N_0 \) be the product of finite ramified primes of \( D \). We introduce the definite Shimura curve \( X = X_{N_0} \) over \( k \) (for maximal orders) in §1, which is a finite union of genus zero curves. Also introduced are the Gross points, which are special points on these curves associated to orders in imaginary quadratic extensions of \( k \). With a natural choice of basis on the Picard group \( \text{Pic}(X) \), the Hecke correspondences can be expressed by Brandt matrices.

From the entries of Brandt matrices we introduce certain theta series. Taking into account the Gross height pairing on the \( \text{Pic}(X) \) (defined in §1.2), we then have at hand a construction of automorphic forms of Drinfeld type for the congruence subgroup \( \Gamma_0(N_0) \) of \( \text{GL}_2(\mathbb{F}_q[t]) \). The main theorem of this article in §2.3 is:

**Theorem.** There is a map \( \Phi : \text{Pic}(X) \times \text{Pic}(X)^\vee \to M^\text{new}(\Gamma_0(N_0)) \) such that for all monic polynomials \( m \) of \( \mathbb{F}_q[t] \)

\[
T_m \Phi(e, e') = \Phi(t_m e, e') = \Phi(e, t_m e').
\]

Here \( \text{Pic}(X)^\vee \) is the dual group \( \text{Hom}(\text{Pic}(X), \mathbb{Z}) \), \( M^\text{new}(\Gamma_0(N_0)) \) is the space of Drinfeld type “new” forms for \( \Gamma_0(N_0) \), \( t_m \) are Hecke correspondences on \( X \), and \( T_m \) are Hecke operators on \( M^\text{new}(\Gamma_0(N_0)) \). Moreover, this map induces an isomorphism (as Hecke modules)

\[
(\text{Pic}(X) \otimes \mathbb{C}) \otimes_{\mathbb{T}_C} (\text{Pic}(X)^\vee \otimes \mathbb{Z} \otimes \mathbb{C}) \cong M^\text{new}(\Gamma_0(N_0)).
\]

This theorem in fact tells us that all automorphic “new” forms of Drinfeld type come from our theta series. The special case of our theorem when \( N_0 \) is single prime is also obtained in Papikian [10] §3, by a different geometric method using Néron models of jacobians of Drinfeld modular curve \( X_0(N_0) \). In our proof of the above theorem, we use the explicit construction of theta series and claim the equality of the trace of the \( m \)-th Brandt matrix \( B(m) \) and the trace of the Hecke operator \( T_m \) on \( M^\text{new}(\Gamma_0(N_0)) \) for each monic polynomial \( m \) in \( \mathbb{F}_q[t] \). This claim is essentially the Jacquet-Langlands correspondence (cf. [9]) between automorphic representations of quaternion algebras over \( k \) and automorphic cuspidal representations of \( \text{GL}_2 \) over \( k \). Another crucial step in the proof is to show that the Hecke module \( M^\text{new}(\Gamma_0(N_0)) \) is free of rank one, which follows from the multiplicity one theorem (cf. [3]). For the sake of completeness, we recall these results in Appendix.
Let $D$ be an irreducible polynomial in $\mathbb{F}_q[t]$ such that $K = k(\sqrt{D})$ is imaginary and $P$ is inert in $K$ if the prime $P$ divides $N_0$. For each ideal class $A$ of $\mathbb{F}_q[t][\sqrt{D}] = O_K$, we construct in §2.4 an automorphic form $g_A$ of Drinfeld type with its Fourier coefficients worked out. In §3.1 we recall Rankin product of $L$-series $\Lambda(f, A, s)$ associated to Drinfeld type new form $f$ for $\Gamma_0(N_0)$ and partial zeta function $\zeta_A$. In §3.2 we express the central critical value $\Lambda(f, A, 0)$ as the Petersson inner product of $f$ and $g_A$. Furthermore, when $f$ is a “normalized” Hecke eigenform and $\chi$ is a character of ideal class group $\text{Pic}(O_K)$ of $O_K$, we give the twisted critical value $\Lambda(f, \chi, 0)$ explicitly in terms of the Gross height of a special divisor class $e_{f, \chi}$ on the definite Shimura curve $X_{N_0}$. This is our analogue of Gross formula.

Let $E$ be an elliptic curve over $k$ with conductor $N_0\infty$ and split multiplicative reduction at $\infty$. From the work of Weil, Jacquet-Langlands, and Deligne, it is well known that there exists a Drinfeld type cusp form $f_E$ such that $L(E/k, s+1) = L(f_E, s)$. Here $L(E/k, s)$ is the Hasse-Weil $L$-series of $E$ over $k$. After doing base change to the quadratic field $K$, one gets $L(E/K, s+1) = \Lambda(f, 1_D, s)$ where $1_D$ is the trivial character of $\text{Pic}(O_K)$. Our formula can certainly be applied to these elliptic curves. An example is given in §3.4.

**Notation**

We fix the following notations:

- $k$: the rational function field $\mathbb{F}_q(t)$, $q = p^{\ell_0}$ where $p$ is an odd prime.
- $A$: the polynomial ring $\mathbb{F}_q[t]$.
- $\infty$: the infinite place, which corresponds to degree valuation $v_\infty$.
- $\pi_\infty$: $t^{-1}$, a fixed uniformizer of $\infty$.
- $k_\infty$: $\mathbb{F}_q((t^{-1}))$, i.e. the completion of $k$ at $\infty$.
- $\mathcal{O}_\infty$: $\mathbb{F}_q[[t^{-1}]]$, i.e. the valuation ring in $k_\infty$.
- $P$: a finite prime (place) of $k$.
- $k_P$: the completion of $k$ at the finite prime $P$.
- $A_P$: the closure of $A$ in $k_P$.
- $\mathcal{A}_k$: the adele ring of $k$.
- $k$: $\prod_P k_P$, the finite adele ring of $k$.
- $\hat{A}$: $\prod_P A_P$.
- $\psi_\infty$: a fixed additive character on $k_\infty$: for $y = \sum_i a_i \pi_\infty^i \in k_\infty$, we define $\psi_\infty(y) := \exp\left(\frac{2\pi \sqrt{-1}}{p} \cdot \text{Tr}_{\mathbb{F}_q/\mathbb{F}_p}(-a_1)\right)$. 

We identify non-zero ideals of $A$ with the monic polynomials in $A$ by using the same notation.

1 Definite Shimura curves

Let $\mathcal{D}$ be a quaternion algebra over $k$ ramified at $\infty$ (call $\mathcal{D}$ “definite”). Before introducing the definite Shimura curve for $\mathcal{D}$, we start with a genus $0$ curve $Y$ over $k$ associated with the quaternion algebra $\mathcal{D}$, which is defined by the following: the points of $Y$ over any $k$-algebra $M$ are

$$Y(M) = \{ x \in \mathcal{D} \otimes_k M : x \neq 0, \text{Tr}(x) = \text{Nr}(x) = 0 \}/\mathcal{D}^\times,$$

where the action of $\mathcal{D}^\times$ on $\mathcal{D} \otimes_k M$ is by multiplication on $M$, $\text{Tr}$ and $\text{Nr}$ are respectively the reduced trace and the reduced norm of $\mathcal{D}$. More precisely, if

$$\mathcal{D} = k + ku + kv + kuv$$

where $u^2 = \alpha, v^2 = \beta, \alpha$ and $\beta$ are in $k^\times$, and $uv = -vu$, then $Y$ is just the conic

$$\alpha y^2 + \beta z^2 = \alpha \beta w^2$$

in the projective plane $\mathbb{P}^2$. The group $\mathcal{D}^\times$ acts on $Y$ (from the right) by conjugation. If $K$ is a quadratic extension of $k$, $Y(K)$ is canonically identified with the set $\text{Hom}(K, \mathcal{D})$ of embeddings: for each embedding $f : K \to \mathcal{D}$, let $y = y_f$ be the image of the unique $K$-line on the quadric $\{ x \in \mathcal{D} \otimes_k K : \text{Tr}(x) = \text{Nr}(x) = 0 \}$ on which conjugation by $f(\mathcal{D}^\times)$ acts by multiplication by the character $a \mapsto a/\bar{a}$. Note that $y_f$ is one of the two fixed points of $f(\mathcal{D}^\times)$ acting on $Y(K)$; another one is the image of the line where conjugation acts by the character $a \mapsto \bar{a}/a$.

Let $N_0$ be the product of the finite ramified primes of $\mathcal{D}$. Choose a maximal $A$-order $R$ of $\mathcal{D}$. For any finite prime $P$ let $R_P := R \otimes_A \hat{A}, \mathcal{D}_P := \mathcal{D} \otimes_k \hat{k}$, and

$$\hat{R} := R \otimes_A \hat{A}, \hat{\mathcal{D}} := \mathcal{D} \otimes_k \hat{k}.$$

DEFINITION 1.1. (cf. [2] and [8]) The definite Shimura curve $X_{N_0}$ is defined as

$$X_{N_0} = \left( \hat{R}^\times \backslash \hat{\mathcal{D}}^\times \times Y \right) /\mathcal{D}^\times.$$

We will use the notation $X$ instead of $X_{N_0}$ when $N_0$ is fixed.

LEMMA 1.2. $X_{N_0}$ is a finite union of curves of genus $0$.

Proof. Let $g_1, \ldots, g_n$ be representatives for the finite double coset space $\hat{R}^\times \backslash \hat{\mathcal{D}}^\times /\mathcal{D}^\times$, i.e.

$$\hat{\mathcal{D}}^\times = \prod_{i=1}^n \hat{R}^\times g_i \mathcal{D}^\times.$$

Then each coset of $X_{N_0}$ has a representative $(\hat{R}^\times g_i, y) \mod \mathcal{D}^\times$ and the map

$$X_{N_0} \to \prod_{i=1}^n Y/\Gamma_i$$

$$(\hat{R}^\times g_i, y) \mapsto y \mod \Gamma_i$$
Theta series and function field analogue of Gross formula

is a bijection, where $\Gamma_i = g_i^{-1} \hat{\mathcal{R}}^\times g_i \cap \hat{\mathcal{D}}^\times$ is a finite group for $i = 1, \ldots, n$. \qed

**Definition 1.3.** Let $K$ be an imaginary quadratic extension of $k$ (i.e. $\infty$ is not split in $K$). We call

$$x = (g, y) \in \text{Image} \left[ \hat{\mathcal{R}}^\times \backslash \hat{\mathcal{D}}^\times \times Y(K) \to X_{N_0}(K) \right]$$

a *Gross point on $X_{N_0}$ over $K$.*

Let $f : K \to \mathcal{D}$ be the embedding corresponding to $y$. Then

$$f(K) \cap g^{-1} \hat{R}g = f(O_d)$$

for some quadratic order $O_d := A[\sqrt{d}]$ where $d$ is an element in $A$ with $d \notin k^2_\infty$.

In this case, we say $x$ is of discriminant $d$. Note that the discriminant of a Gross point is well-defined up to multiplying with elements in $(\mathcal{F} \times)^2$. Set $X_i := Y/\Gamma_i$.

If the component $g$ of a Gross point $x$ is congruent to $g_i$ in $\hat{\mathcal{R}}^\times \backslash \hat{\mathcal{D}}^\times / \hat{\mathcal{D}}^\times$, then $x$ lies on the component $X_i(K) = (Y/\Gamma_i)(K)$.

### 1.1 Actions on Gross points

Let $a \in \hat{K}^\times$ where $\hat{K} := K \otimes_k \hat{k}$ and $x = (g, y)$ be a Gross point of discriminant $d$. Let $f : K \to \mathcal{D}$ be the embedding corresponding to $y$. This induces a homomorphism $\hat{f} : \hat{K} \to \hat{\mathcal{D}}$ and we define

$$x_a := (g\hat{f}(a), y).$$

Note that $x_a$ is also of discriminant $d$, and it is easy to check that $x = x_a$ if and only if $a \in \hat{O}_d \hat{K}^\times$ where $\hat{O}_d := O_d \otimes_A \hat{A}$. Hence $\hat{O}_d^\times \backslash \hat{K}^\times / K^\times \cong \text{Pic}(O_d)$ acts freely on the set $G_d$ of Gross points of discriminant $d$.

The orbit space $G_d / \text{Pic}(O_d)$ is identified with the space of double cosets

$$\hat{R}^\times \backslash \hat{\mathcal{E}} / \hat{f}(\hat{K}^\times),$$

where $f : K \to \mathcal{D}$ is a fixed embedding (if any exist) and

$$\mathcal{E} := \{g \in \hat{\mathcal{D}}^\times : f(K) \cap g^{-1} \hat{R}g = f(O_d)\}.$$

Note that

$$\hat{R}^\times \backslash \hat{\mathcal{E}} / \hat{f}(\hat{K}^\times) \cong \prod_P R_P^\times \backslash \mathcal{E}_P / f(K_P^\times)$$

where $\mathcal{E}_P := \{g_P \in \mathcal{D}_P^\times : f(K_P) \cap g_P^{-1} R_P g_P = f(O_{d,P})\}$ and $O_{d,P}$ is the closure of $O_d$ in $K_P := K \otimes_k k_P$. 

Lemma 1.4. (cf. [16] or [17])

\[
\#(R^*_P \setminus \mathcal{E}_P / f(K^*_P)) = \begin{cases} 1 & \text{if } P \nmid N_0, \\ 1 - \{ \frac{d}{P} \} & \text{if } P | N_0. \end{cases}
\]

Here \( \{ \frac{d}{P} \} \) is the Eichler quadratic symbol, i.e.

\[
\{ \frac{d}{P} \} = \begin{cases} 1 & \text{if } P^2 | d \text{ or } d \mod P \in ((A/P)^\times)^2, \\ -1 & \text{if } d \mod P \in (A/P)^\times - ((A/P)^\times)^2, \\ 0 & \text{if } P | d \text{ but } P^2 \not| d. \end{cases}
\]

Remark. The above lemma tells us that the number \( \#(G_d) \) is equal to

\[
h(d) \prod_{P | N_0} \left( 1 - \left\{ \frac{d}{P} \right\} \right)
\]

where \( h(d) \) is the class number of \( O_d \).

There is a natural action of \( \text{Gal}(K/k) \) on Gross points in the following way: let \( x = (g, y) \) be a Gross point and \( f_y : K \hookrightarrow \mathcal{D} \) be the embedding corresponding to \( y \). Define

\[x^\sigma = (g, y)^\sigma = (g, y_\sigma)\]

where \( \sigma \in \text{Gal}(K/k) \) and \( y_\sigma \) corresponds to the embedding \( f_y \circ \sigma \). If \( x \) is a Gross point of discriminant \( d \) in \( X_i \), then so is \( x^\sigma \). Moreover, let \( a \in \hat{O}_d^\times \setminus \hat{K}^\times / K^\times \cong \text{Pic}(O_d) \) and \( \sigma \in \text{Gal}(K/k) \) one has

\[(x^\sigma)_a = (x_{\sigma(a)})^\sigma.\]

Therefore we have an action of \( \text{Pic}(O_d) \times \text{Gal}(K/k) \) on the set \( G_d \) of Gross points of discriminant \( d \).

1.2 Hecke correspondences and Gross height pairing

Let \( P \) be a prime of \( A \). Let \( \mathcal{T} \) be the Bruhat-Tits tree of \( \text{PGL}_2(k_P) \) as defined in [14]. The vertices are the equivalence classes of \( A_P \)-lattices \( L \) in \( k_P^2 \), and two such vertices \([L] \) and \([L'] \) are adjacent if there exists an integer \( r \) such that

\[P^{r+1}L \subsetneq L' \subsetneq P^rL.\]

This is a tree where each vertex has degree \( q^\deg P + 1 \). For a vertex \( v \), the Hecke correspondence \( t_P \) sends \( v \) to the formal sum of its \( q^\deg P + 1 \) neighbors in the tree. Identifying \( \text{PGL}_2(A_P) \setminus \text{PGL}_2(k_P) \) with the Bruhat-Tits tree, we can write the Hecke correspondence for \( g \in \text{PGL}_2(A_P) \setminus \text{PGL}_2(k_P) \):

\[t_P(g) := \sum_{\deg(u) < \deg P} \begin{pmatrix} 1 & u \\ 0 & P \end{pmatrix} g + \begin{pmatrix} P & 0 \\ 0 & 1 \end{pmatrix} g.\]
Note that $X_{N_0}$ can be written as
\[
(R^\times \backslash \hat{D}^\times /\hat{k}^\times) \times Y/\mathcal{D}^\times
\]
and
\[
R^\times \backslash \hat{D}^\times /\hat{k}^\times = \prod_p' R_p^\times \backslash \mathcal{D}_p^\times /k_p^\times.
\]
When $(P, N_0) = 1$,
\[
R_p^\times \backslash \mathcal{D}_p^\times /k_p^\times \cong \text{PGL}_2(A_P) \backslash \text{PGL}_2(k_P)
\]
and so we have the Hecke correspondence $t_P$ on $X_{N_0}$.

Now suppose $P$ divides $N_0$, then $R_p^\times \backslash \mathcal{D}_p^\times /k_p^\times$ has two elements and define the Atkin-Lehner involution
\[
(\hat{g}, y) := (\hat{g}', y)
\]
where $\hat{g}'$ is another double coset in $R_p^\times \backslash \mathcal{D}_p^\times /k_p^\times$.

From the construction, these correspondences commute with each other. Therefore we can define Hecke correspondence $t_m$ for every non-zero ideal $(m)$ of $A$ in the following way:

\[
\begin{cases}
t_{mm'} = t_m t_{m'} & \text{if } m \text{ and } m' \text{ are relatively prime}, \\
t_{P^\ell} = t_{P^\ell-1} t_P - q^{\deg P} t_{P^\ell-2} & \text{for } P \nmid N_0, \\
t_{P^\ell} = w^\ell_P & \text{for } P \mid N_0.
\end{cases}
\]

Note that $X = X_{N_0} = \bigcup_{i=1}^n X_i$, where $n$ is the left ideal class number of $R$. Consider the Picard group $\text{Pic}(X)$, which is isomorphic to $\mathbb{Z}^n$ and is generated by the classes $e_i$ of degree 1 corresponding to the component $X_i$. Then the correspondences $t_m$ induce endomorphisms of the group $\text{Pic}(X)$. In fact, with respect to the basis $\{e_1, ..., e_n\}$, these endomorphisms can be represented by Brandt matrices.

Let $\{I_1, ..., I_n\}$ be a set of left ideals of $R$ representing the distinct ideal classes, with $I_1 = R$. Let $w_i := \#(R_i^\times)/(q - 1)$ where $R_i$ is the right order of $I_i$. Consider $M_{ij} := I_j^{-1} I_i$, which is a left ideal of $R_j$ with right order $R_i$. Choose a generator $N_{ij} \in k$ of the reduced ideal norm $\text{Nr}(M_{ij})(:= < \text{Nr}(b) : b \in M_{ij} >_A)$ of $M_{ij}$. For each monic polynomial $m$ in $A$, define
\[
B_{ij}(m) := \frac{\# \{ b \in M_{ij} : \text{Nr}(b)/N_{ij} = (m) \}}{(q - 1)w_j}
\]
and the $m$-th Brandt matrix
\[
B(m) := \left( B_{ij}(m) \right)_{1 \leq i, j \leq n} \in \text{Mat}_n(\mathbb{Z}).
\]
For all non-zero ideal \((m)\) in \(A\) and \(i = 1, 2, \ldots, n\),
\[ t_m e_i = \sum_{j=1}^{n} B_{ij}(m) e_j. \]

**Proof.** From the definition of \(t_m\) and the recurrence relations of \(B(m)\) (cf. [16]), we can reduce the proof to the case when \(m = P\) is a prime. From the following bijection
\[
\mathcal{R}^x \times \mathcal{D}^x \cong \{ \text{left ideals of } R \}
\]
\[
\mathcal{R}^x g \leftrightarrow I_g := \mathcal{R}g \cap \mathcal{D},
\]
for any element \(g\) in \(\mathcal{D}^x\) we can identify the following set
\[
\left\{ \mathcal{R}^x \begin{pmatrix} 1 & u \\ 0 & P \end{pmatrix} g : \deg u < \deg P \right\} \cup \left\{ \mathcal{R}^x \begin{pmatrix} P & 0 \\ 0 & 1 \end{pmatrix} g \right\}
\]
with
\[
\{ \text{left ideal } I \text{ of } R \text{ contained in } I_g \text{ with } \text{Nr}(I) = P \text{Nr}(I_g) \}. \]
According to the definition of \(t_P\), \(t_P e_i = \sum_j \alpha_j e_j\) where \(\alpha_j\) is the number of left ideals \(I\) of \(R\) equivalent to \(I_j\) which are contained in \(I_i\) with \(\text{Nr}(I) = P \text{Nr}(I_i)\). It is easy to see that \(\alpha_j = B_{ij}(P)\) and so the proposition holds. \(\square\)

We define the *Gross height pairing* \(<\cdot,\cdot>\) on \(\text{Pic}(X)\) with values in \(\mathbb{Z}\) by setting
\[
\begin{cases}
<e_i, e_j> = 0 & \text{if } i \neq j, \\
<e_i, e_i> = w_i,
\end{cases}
\]
and extending bi-additively. Therefore \(\text{Pic}(X)^\vee := \text{Hom}(\text{Pic}(X), \mathbb{Z})\) can be viewed as a subgroup of \(\text{Pic}(X) \otimes \mathbb{Q}\) with basis \(\{e_i := e_i/w_i : i = 1, \ldots, n\}\) via this pairing. Since \(w_j B_{ij}(m) = w_i B_{ji}(m)\), one has the following proposition.

**Proposition 1.6.** For all classes \(e\) and \(e'\) in \(\text{Pic}(X)\), we have
\[<t_m e, e'> = <e, t_m e'>.\]

**Proof.** Since \(w_j B_{ij}(m) = w_i B_{ji}(m)\), we have
\[<t_m e_i, e_j> = <e_i, t_m e_j>.\]
for all \(i, j\) and the result holds. \(\square\)

Let \(d \in A\) with \(d \notin k^*_x\). Assume every prime factor \(P\) of \(N_0\) is not split in \(K\) and \(P^2\) does not divides \(d\) (i.e. the set \(G_d\) of Gross points of discriminant \(d\) is not empty). For any prime \(P | N_0\), one has \(w_P(G_d) = G_d\). Suppose \(P_1, \ldots, P_r\) are primes dividing \(N_0\) and inert in \(K\). We have in fact a free
theta series and function field analogue of Gross formula

action of \(\text{Pic}(O_d) \times \prod_{i=1}^r (w_{P_i})\) on \(G_d\). Since \(w_{P_i}\) are of order 2 for all \(i\), \(\text{Pic}(O_d) \times \prod_{i=1}^r (w_{P_i})\) acts simply transitively on \(G_d\).

Let \(a \in A\) with \(a \not\in k_\infty^2\). Consider the rational divisor

\[
c_a := \sum_{a = df^2, f \text{ monic}} \frac{1}{2u(d)} \sum_{x_d \in G_d} x_d.
\]

Here \(u(d) = \#(O_d^\times)\). By calculation one has

\[
\deg(c_a) = \frac{1}{2} \sum_{a = df^2, f \text{ monic}} \left[ \frac{h(d)}{u(d)} \prod_{P|N_0} (1 - \left\{ \frac{d}{P} \right\}) \right].
\]

Let \(e_a \in \text{Pic}(X) \otimes \mathbb{Q}\) be the class of the divisor \(c_a\). It can be shown that

**Proposition 1.7.** The class \(e_a\) lies in \(\text{Pic}(X)^\vee\), which is considered as a subgroup of \(\text{Pic}(X) \otimes \mathbb{Q}\).

Note that we can extend the Gross height pairing to \(\text{Pic}(X) \otimes \mathbb{Q}\) which is linear in the first term and conjugate linear in the second. In the next section this pairing gives us a construction of automorphic forms of Drinfeld type.

2 Automorphic forms of Drinfeld type and main theorem

2.1 Automorphic forms of Drinfeld type

Consider the open compact subgroup \(X_0(N_\infty) := \prod_P X_{0,P} \times \Gamma_\infty\) of \(GL_2(A_k)\), where

\[
X_{0,P} := \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in GL_2(A_P) : c \in NA_P \right\}
\]

for finite prime \(P\), and

\[
\Gamma_\infty := \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in GL_2(\mathcal{O}_\infty) : c \in \pi_\infty \mathcal{O}_\infty \right\}.
\]

An automorphic form \(f\) on \(GL_2(A_k)\) for \(X_0(N_\infty)\) (with trivial central character) is a \(\mathbb{C}\)-valued function on the double coset space

\[
GL_2(k) \backslash GL_2(A_k)/X_0(N_\infty)k_\infty^\times.
\]

Note that by strong approximation theorem (cf. [16]) we have the following bijection

\[
GL_2(k) \backslash GL_2(A_k)/K_0(N_\infty)k_\infty^\times \cong \Gamma_0(N) \backslash GL_2(k_\infty)/\Gamma_\infty k_\infty^\times.
\]
where
\[ \Gamma_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{GL}_2(A) : c \equiv 0 \mod N \right\}. \]

Therefore \( f \) can be viewed as a \( \mathbb{C} \)-valued function on \( \Gamma_0(N) \setminus \text{GL}_2(k_\infty)/\Gamma_\infty k_\infty^\times \). From now on, we call \( f \) an automorphic form for \( \Gamma_0(N) \) if \( f \) is a function on the space of double cosets \( \Gamma_0(N) \setminus \text{GL}_2(k_\infty)/\Gamma_\infty k_\infty^\times \). An automorphic form \( f \) for \( \Gamma_0(N) \) is called a cusp form if for every \( g_\infty \in \text{GL}_2(k_\infty) \) and \( \gamma \in \text{GL}_2(A) \)
\[
\int_{A \setminus k_\infty} f \left( \begin{array}{cc} 1 & h_\gamma x \\ 0 & 1 \end{array} \right) g_\infty \, dx = 0.
\]

Here \( du \) is a Haar measure with \( \int_{A \setminus k_\infty} du = 1 \) and \( h_\gamma \) is a generator of the ideal of \( A \) which is maximal for the property that
\[
\gamma \begin{pmatrix} 1 & h_\gamma A \\ 0 & 1 \end{pmatrix} \gamma^{-1} \subset \Gamma_0(N).
\]

Note that the coset space \( \text{GL}_2(k_\infty)/\Gamma_\infty k_\infty^\times \) can be represented by the two disjoint sets
\[
\mathcal{T}_+ := \left\{ \begin{pmatrix} \pi^r & u \\ 0 & 1 \end{pmatrix} : r \in \mathbb{Z}, u \in k_\infty/\pi_\infty^r O_\infty \right\}
\]
and
\[
\mathcal{T}_- := \left\{ \begin{pmatrix} \pi^r & u \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ \pi_\infty & 0 \end{pmatrix} : r \in \mathbb{Z}, u \in k_\infty/\pi_\infty^r O_\infty \right\}.
\]

**Definition 2.1.** An automorphic form \( f \) on \( \text{GL}_2(k_\infty) \) is of Drinfeld type if it satisfies the following harmonic properties: for any \( g_\infty \in \text{GL}_2(k_\infty) \) we have
\[
\tilde{f}(g_\infty) := f(g_\infty \begin{pmatrix} 0 & 1 \\ \pi_\infty & 0 \end{pmatrix}) = -f(g_\infty) \quad \text{and} \quad \sum_{\kappa \in \text{GL}_2(O_\infty)/\Gamma_\infty} f(g_\infty \kappa) = 0.
\]

Suppose a function \( f : (1 \ A) \setminus \text{GL}_2(k_\infty)/\Gamma_\infty k_\infty^\times \to \mathbb{C} \) is given. Recall the *Fourier expansion of* \( f \) (cf. [18]): for \( r \in \mathbb{Z} \) and \( u \in k_\infty \),
\[
f \left( \begin{pmatrix} \pi^r & u \\ 0 & 1 \end{pmatrix} \right) = \sum_{\lambda \in A} f^*(r, \lambda) \psi_\infty(\lambda u)
\]
where
\[
f^*(r, \lambda) := \int_{A \setminus k_\infty} f \left( \begin{pmatrix} \pi^r & u \\ 0 & 1 \end{pmatrix} \right) \psi_\infty(-\lambda u) \, du.
\]
Here $\psi_\infty$ is the fixed additive character on $k_\infty$ in the notation table. Since $f(g\gamma) = f(g)$ for all $\gamma_\infty \in \Gamma_\infty$, $f^*(r, \lambda) = 0$ if $\deg \lambda + 2 > r$. Moreover, if $f$ satisfies harmonic properties, then

$$f^*(r, \lambda) = q^{-r + \deg \lambda + 2} f^*(\deg \lambda + 2, \lambda)$$

if $\deg \lambda + 2 \leq r$.

2.1.1 Example: Theta series

Fix a definite quaternion algebra $D = D_{(N_0)}$ where $N_0$ is the product of finite ramified primes of $D$. Let $\mathcal{R}$ be a maximal order and $n$ be the class number. With representatives of left ideal classes fixed in §1.2, we have introduced for each $(i, j)$, the ideal $M_{ij}$ of $D$ and chose a generator $N_{ij}$ of the fractional ideal $\text{Nr}(M_{ij})$. For $1 \leq i, j \leq n$ and $(x, y) \in k_\infty \times k_\infty$, define

$$\theta_{ij}(x, y) := \sum_{b \in M_{ij}} \phi_\infty \left( \frac{\text{Nr}(b)}{N_{ij}} xt^2 \right) \cdot \psi_\infty \left( \frac{\text{Nr}(b)}{N_{ij}} y \right),$$

where $\phi_\infty$ is the characteristic function of $\mathcal{O}_\infty$. It is easy to obtain the following properties:

1. $\theta_{ij}(x, y) = \sum_{\lambda \in A, \deg \lambda + 2 \leq v_\infty(x)} B'_{ij}(\lambda) \psi_\infty(\lambda y)$

where for each $\lambda \in A$,

$$B'_{ij}(\lambda) = \# \{ b \in M_{ij} : \text{Nr}(b)/N_{ij} = \lambda \}.$$

2. $\theta_{ij}(x, y + h) = \theta_{ij}(x, y)$ for $h \in A$.
3. $\theta_{ij}(\alpha x, \beta x + y) = \theta_{ij}(x, y)$ for $\alpha \in O_\infty^\times$, $\beta \in O_\infty$.

Basing on Poisson summation formula, we have the following transformation law for $\theta_{ij}$ (cf. Appendix B):

**Proposition 2.2.** Let $(x, y) \in k_\infty^\times \times k_\infty$ and $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(A)$. Suppose $v_\infty(cx) > v_\infty(cy + d)$ and $c \equiv 0 \mod N_0$. Then for $1 \leq i, j \leq n$,

$$\theta_{ij} \left( \frac{x}{(cy + d)^2}, \frac{ay + b}{cy + d} \right) = q^{-2v_\infty(cy + d)} \cdot \theta_{ij}(x, y).$$

For $g_\infty \in \text{GL}_2(k_\infty)$, write $g_\infty$ as $\gamma \begin{pmatrix} x & y \\ 0 & 1 \end{pmatrix} \gamma_\infty z_\infty$, where $\gamma$ is in $\Gamma_0(N_0)$, $(x, y)$ is in $k_\infty^\times \times k_\infty$, $\gamma_\infty$ is in $\Gamma_\infty$, and $z_\infty$ is in $k_\infty^\times$. We introduce the theta series
\( \Theta_{ij} \) for \( M_{ij} \):

\[
\Theta_{ij}(g_\infty) := \frac{1}{(q-1)w_j} \cdot q^{-v_\infty(x)} \cdot \left( \sum_{\epsilon \in \mathbb{F}_q} \theta_{ij}(x, \epsilon y) \right)
\]

\[
= q^{-v_\infty(x)} \cdot \left[ \frac{1}{w_j} + \sum_{m \in A \text{monic, } \deg m + 2 \leq v_\infty(x)} B_{ij}(m) \left( \sum_{\epsilon \in \mathbb{F}_q} \psi_\infty(\epsilon m y) \right) \right].
\]

The last equality follows from \( B_{ij}'(0) = 1 \) and for each monic polynomial \( m \in A \),

\[
(q-1)w_j \cdot B_{ij}(m) = \sum_{\epsilon \in \mathbb{F}_q} B_{ij}'(\epsilon m).
\]

The transformation law of \( \theta_{ij} \) tells us that

**Lemma 2.3.** \( \Theta_{ij} \) is a well-defined \( \mathbb{Q} \)-valued function on the double coset space \( \Gamma_0(N_0) \setminus \text{GL}_2(k_\infty) / \Gamma_\infty k_\infty^\times \).

**Proof.** Let \( g_\infty \) be an element in \( \text{GL}_2(k_\infty) \). Suppose

\[
g_\infty = \gamma_1 \begin{pmatrix} x_1 & y_1 \\ 0 & 1 \end{pmatrix} \gamma_{\infty,1} z_1 = \gamma_2 \begin{pmatrix} x_2 & y_2 \\ 0 & 1 \end{pmatrix} \gamma_{\infty,2} z_2,
\]

where for \( i = 1, 2, \gamma_i \in \Gamma_0(N_0), (x_i, y_i) \in k_\infty \times k_\infty^\times, \gamma_{\infty,i} \in \Gamma_\infty, z_i \in k_\infty^\times \). We need to show that

\[
q^{-v_\infty(x_1)} \cdot \left( \sum_{\epsilon \in \mathbb{F}_q} \theta_{ij}(x_1, \epsilon y_1) \right) = q^{-v_\infty(x_2)} \cdot \left( \sum_{\epsilon \in \mathbb{F}_q} \theta_{ij}(x_2, \epsilon y_2) \right).
\]

Set \( \gamma = \gamma_2^{-1} \gamma_1 = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, z = z_2^{-1} z_1, \) and \( \gamma_\infty = \gamma_{\infty,1}^{-1} \gamma_{\infty,2} \). Then one has

\( v_\infty(cx_1) > v_\infty(cy_1 + d) \) and

\[
\gamma \begin{pmatrix} x_1 & y_1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} \det \gamma \cdot x_1 + cy_1 + d \\ 0 \\ \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} x_2 & y_2 \\ 0 & 1 \end{pmatrix}, \gamma_{\infty,2} z.
\]

Therefore \( v_\infty(x_2) = v_\infty(x_1) - 2v_\infty(cy_1 + d) \), and the properties of \( \theta_{ij} \) implies

\[
\theta_{ij}(x_2, \epsilon y_2) = \theta_{ij} \left( \frac{\det \gamma \cdot x_1 + cy_1 + d}{(cy_1 + d)^2}, \epsilon y_1 + \frac{ay_1 + b}{cy_1 + d} \right).
\]
Theta series and function field analogue of Gross formula

for each \( \epsilon \in \mathbb{F}_q^\times \). Hence the transformation law of \( \theta_{ij} \) in Proposition 2.2 shows

\[
q^{-v_\infty(x_2)} \left( \sum_{\epsilon \in \mathbb{F}_q^\times} \theta_{ij}(x_2, c\epsilon y_2) \right) = q^{-v_\infty(x_1)} \left( \sum_{\epsilon \in \mathbb{F}_q^\times} \theta_{ij}(\det \gamma \cdot x_1, \epsilon \det \gamma \cdot y_1) \right)
\]

\[
= q^{-v_\infty(x_1)} \left( \sum_{\epsilon \in \mathbb{F}_q^\times} \theta_{ij}(x_1, \epsilon y_1) \right).
\]

\[
\square
\]

The Fourier coefficients of \( \Theta_{ij} \) can be easily read off from Brandt matrices: for each \( r \in \mathbb{Z} \) and \( \lambda \in A \) with \( \deg \lambda + 2 \leq r \) the Fourier coefficients

\[
\Theta^*_{ij}(r, \lambda) = \begin{cases} q^{-r} B_{ij}(m) & \text{if } (\lambda) = (m) \neq 0, \\ q^{-r}/w_j & \text{if } \lambda = 0. \end{cases}
\]

Therefore \( \Theta^*_{ij}(r + 1, \lambda) = q^{-1} \Theta^*_{ij}(r, \lambda) \) for all \( \lambda \in A \) with \( \deg \lambda + 2 \leq r \).

In fact, \( \Theta_{ij} \) are of Drinfeld type for all \( 1 \leq i, j \leq n \). To show the harmonicity of \( \Theta_{ij} \), by \cite{6} Lemma 2.13, it is enough to prove that for all \( g_\infty \in \text{GL}_2(k_\infty) \)

\[
\tilde{\Theta}_{ij}(g_\infty) = -\Theta_{ij}(g_\infty).
\]

Let \( \pi_\infty^r \in k_\infty^\times \) and \( u \in k_\infty \). Choose \( c, d \in A \) with \( c \equiv 0 \mod N_0 \), \( (c, d) = 1 \), \( v_\infty(u + \frac{d}{c}) \geq r + 1 \), and find \( a, b \in A \) with \( ad - bc = 1 \). Then for \( \ell \in \mathbb{Z} \) with \( \ell \leq r + 1 \) the following two matrices:

\[
\left( \begin{array}{cc} \pi_\infty^\ell & u \\ 0 & 1 \end{array} \right) \left( \begin{array}{cc} 0 & 1 \\ \pi_\infty & 0 \end{array} \right) \text{ and } \left( \begin{array}{cc} d & -b \\ -c & a \end{array} \right) \left( \begin{array}{cc} \pi_\infty^{1-\ell} & \frac{1}{c} \\ 0 & 1 \end{array} \right)
\]

represent the same coset in \( \text{GL}_2(k_\infty)/\Gamma_\infty k_\infty^\times \). Using this fact for \( \ell = r \) and \( \ell = r + 1 \) one obtains

\[
\tilde{\Theta}_{ij} \left( \begin{array}{cc} \pi_\infty^r & u \\ 0 & 1 \end{array} \right) - q^{-1} \Theta_{ij} \left( \begin{array}{cc} \pi_\infty^{r+1} & u \\ 0 & 1 \end{array} \right) = \sum_{\deg \mu = 2 = 1-r+2 \deg c} \Theta^*_{ij}(1 - r + 2 \deg c, \mu) \psi_\infty(\mu \frac{a}{c}).
\]

Set \( u_\epsilon := -\frac{d}{c} + \epsilon \pi_\infty^r \) for \( \epsilon \in \mathbb{F}_q^\times \). From the identity

\[
\frac{a}{c} - \frac{1}{c^2 \epsilon \pi_\infty^r} = \frac{au_\epsilon + b}{cu_\epsilon + d},
\]
and summing over all \( \epsilon \) we get:

\[
(q - 1) \tilde{\Theta}_{ij} \begin{pmatrix} \pi_{\infty}^r & u \\ 0 & 1 \end{pmatrix} - \sum_{\epsilon \in \mathbb{F}_q^*} \Theta_{ij} \begin{pmatrix} \pi_{\infty}^{1-r} & \frac{au + b}{cu + d} \\ 0 & 1 \end{pmatrix}
\]

\[
= q \sum_{\deg \mu + 2 = 1 - r + 2 \deg c} \Theta_{ij}^* (1 - r + 2 \deg c, \mu) \psi_\infty(\mu \frac{a}{c}).
\]

Note that

\[
\begin{pmatrix} \pi_{\infty}^1 & \frac{au + b}{cu + d} \\ 0 & 1 \end{pmatrix} \text{ and } \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \pi_{\infty}^r & u \\ 0 & 1 \end{pmatrix}
\]

represent the same coset in \( \text{GL}_2(k_\infty) / \Gamma_\infty k_\infty^\times \). Thus one has

\[
\tilde{\Theta}_{ij} \begin{pmatrix} \pi_{\infty}^{r+1} & u \\ 0 & 1 \end{pmatrix} - \tilde{\Theta}_{ij} \begin{pmatrix} \pi_{\infty}^r & u \\ 0 & 1 \end{pmatrix} = \sum_{\epsilon \in \mathbb{F}_q^*} \Theta_{ij} \begin{pmatrix} \pi_{\infty}^{r+1} & u + \epsilon \pi_{\infty}^r \\ 0 & 1 \end{pmatrix}.
\]

From the Fourier expansion of \( \tilde{\Theta}_{ij} \) and \( \Theta_{ij} \) we have that for \( \lambda \in A \) with \( \deg \lambda + 2 \leq r \),

\[
\tilde{\Theta}_{ij}^*(r + 1, \lambda) - \tilde{\Theta}_{ij}^*(r, \lambda) = (q - 1) \Theta_{ij}^*(r + 1, \lambda),
\]

and for \( \deg \lambda + 2 = r + 1 \),

\[
\tilde{\Theta}_{ij}^*(\deg \lambda + 2, \lambda) = -\Theta_{ij}^*(r + 1, \lambda).
\]

Therefore \( \tilde{\Theta}_{ij}^*(r, \lambda) = -\Theta_{ij}^*(r, \lambda) \) for \( \lambda \in A \) with \( \lambda \neq 0 \) and \( r \geq \deg \lambda + 2 \).

To compute \( \tilde{\Theta}_{ij}^*(r, 0) \), note that

\[
\tilde{\Theta}_{ij} \begin{pmatrix} \pi_{\infty}^r & 0 \\ 0 & 1 \end{pmatrix} = \sum_{\deg \lambda \leq r - 2} \tilde{\Theta}_{ij}^*(r, \lambda)
\]

\[
= \tilde{\Theta}_{ij}^*(r, 0) + \sum_{\lambda \neq 0, \deg \lambda \leq r - 2} -\Theta_{ij}^*(r, \lambda).
\]

On the other hand, for any \( \epsilon \in \mathbb{F}_q^* \) and \( \ell \geq 0 \) the following two matrices

\[
\begin{pmatrix} \pi_{\infty}^{\deg N_0 + \ell} & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ \pi_{\infty} & 0 \end{pmatrix}, \quad \begin{pmatrix} \epsilon^{-1} & -1 \\ -\epsilon^{t^\ell N_0} & \epsilon(t^\ell N_0 + 1) \end{pmatrix} \begin{pmatrix} \pi_{\infty}^{1 - \deg N_0 - \ell} & (t^\ell N_0)^s \epsilon(t^\ell N_0 + 1) \\ 0 & 1 \end{pmatrix}
\]

represent the same coset in \( \text{GL}_2(k_\infty) / \Gamma_\infty k_\infty^\times \). Therefore

\[
\tilde{\Theta}_{ij} \begin{pmatrix} \pi_{\infty}^{\deg N_0 + \ell} & 0 \\ 0 & 1 \end{pmatrix} = \sum_{\deg \lambda \leq \deg N_0 + \ell - 1} \Theta_{ij}^*(\deg N_0 + \ell + 1, \lambda) \psi_\infty(\lambda \frac{\epsilon}{t^\ell N_0}).
\]
\begin{align*}
\sum_{\deg \lambda \leq \deg N + \ell - 2} \Theta^*_{ij}(\deg N_0 + \ell + 1, \lambda) & - \frac{1}{q - 1} \sum_{\deg \lambda = \deg N_0 + \ell - 1} \Theta^*_{ij}(\deg N_0 + \ell + 1, \lambda).
\end{align*}

This gives
\begin{align*}
\tilde{\Theta}^*_{ij}(\deg N_0 + \ell, 0) \\
= \left( \Theta^*_{ij}(\deg N_0 + \ell + 1, 0) + (1 + q) \sum_{\lambda \neq 0, \deg \lambda \leq \deg N_0 + \ell - 2} \Theta^*_{ij}(\deg N_0 + \ell + 1, \lambda) \right) \\
- \frac{1}{q - 1} \sum_{\deg \lambda = \deg N_0 + \ell - 1} \Theta^*_{ij}(\deg N_0 + \ell + 1, \lambda).
\end{align*}

Using the fact that \( M_{ij} \) is discrete and cocompact in \( \mathcal{D}_\infty = \mathcal{D} \otimes_k k_\infty \), it can be deduced that for sufficiently large \( s \) one has
\begin{align*}
q \Theta_{ij} \left( \pi_{\infty}^s \begin{matrix} 0 & \pi_{\infty}^s \\ 1 & 1 \end{matrix} \right) = \Theta_{ij} \left( \pi_{\infty}^{s+1} \begin{matrix} 0 & 0 \\ 1 & 1 \end{matrix} \right).
\end{align*}

Thus from the equality \( \tilde{\Theta}^*_{ij}(r + 1, 0) - \tilde{\Theta}^*_{ij}(r, 0) = (q - 1) \Theta^*_{ij}(r + 1, 0) \) for all \( r \in \mathbb{Z} \) one has
\( \tilde{\Theta}^*_{ij}(r, 0) = - \Theta^*_{ij}(r, 0) \).

Comparing the Fourier coefficients we obtain \( \tilde{\Theta}_{ij} = - \Theta_{ij} \) and hence \( \Theta_{ij} \) is of Drinfeld type for any \( 1 \leq i, j \leq n \).

\section{Hecke Operators}

Let \( f \) be an automorphic form on \( GL_2(k_\infty) \) for \( \Gamma_0(N) \). For each prime \( P \) of \( A \), the \textit{Hecke operator} \( T_P \) is defined by:
\begin{align*}
T_P f(g) & := \sum_{\deg u < \deg P} f \left( \begin{matrix} 1 & u \\ 0 & P \end{matrix} \right) \cdot g + f \left( \begin{matrix} P & 0 \\ 0 & 1 \end{matrix} \right) \cdot g & \text{if } P \nmid N, \\
T_P f(g) & := \sum_{\deg u < \deg P} f \left( \begin{matrix} 1 & u \\ 0 & P \end{matrix} \right) \cdot g & \text{if } P | N.
\end{align*}

Note that the Fourier coefficients of \( T_P f \) are of the form:
\begin{align*}
(T_P f)^*(r, \lambda) & = q^{\deg(P)} \cdot f^*(r + \deg(P), P\lambda) + f^*(r - \deg(P), \frac{1}{P}) & \text{if } P \nmid N, \\
(T_P f)^*(r, \lambda) & = q^{\deg(P)} \cdot f^*(r + \deg(P), P\lambda) & \text{if } P | N.
\end{align*}
Here \( f^*(\pi_r^*, \frac{1}{\pi}) = 0 \) if \( P \nmid \lambda \). Since \( T_P \) and \( T_{P'} \) commute, we can define Hecke operators \( T_m \) for monic polynomial \( m \) in \( A \) as follows:

\[
\begin{cases} 
T_{mm'} = T_m T_{m'} & \text{if } m \text{ and } m' \text{ are relatively prime}, \\
T_{P \ell} = T_{P \ell-1} T_P - q^{\deg P} T_{P \ell-2} & \text{for } P \nmid N, \\
T_{P \ell} = T_P^\ell & \text{for } P \mid N.
\end{cases}
\]

We point out that if \( f \) is of Drinfeld type, then so is \( T_m f \) for any monic polynomial \( m \) (cf. [7] Section 4.9).

When \( T_m \) acts on \( \Theta_{i \ell} \), we get:

**Proposition 2.4.** For any monic polynomial \( m \) in \( A \),

\[
T_m \Theta_{i \ell} = \sum_{\ell} B_i \ell(m) \Theta_{j \ell} = \sum_{\ell} B_{\ell j}(m) \Theta_{i \ell}.
\]

**Proof.** The second identity will follow from the first, as \( w_j \Theta_{i \ell} = w_i \Theta_{j \ell} \) and \( w_\ell B_i \ell(m) = w_i B_\ell j(m) \).

Note that the Hecke operators \( T_m \) satisfy the same relations as the matrices \( B(m) \). Moreover, from the recurrence relations of Brandt matrices (cf. [10]) we have

\[
\sum_{\ell} B_{i \ell}(P) B_{\ell j}(m) = B_{i j}(mP) + q^{\deg(P)} B_{i j}(m/P) \text{ if } P \nmid N_0,
\]

\[
\sum_{\ell} B_{i \ell}(P) B_{\ell j}(m) = B_{i j}(mP) \text{ if } P \mid N_0.
\]

Comparing the Fourier coefficients the result holds.

**Remark.** Let \( E_{N_0} := \sum_{j=1}^{n} \Theta_{i j} \) (which is independent of the choice of \( i \)). For \( r \in \mathbb{Z} \) and \( \lambda \in A \) with \( \deg \lambda + 2 \leq r \) the Fourier coefficients are

\[
E_{N_0}^*(r, \lambda) = q^{-r} \sigma(\lambda)_{N_0}
\]

where

\[
\sigma(\lambda)_{N_0} = \sum_{m|\lambda \text{ monic}} q^{\deg m},
\]

and

\[
E_{N_0}^*(r, 0) = q^{-r} \sum_{j=1}^{n} \frac{1}{w_j}.
\]
Moreover, from Proposition 2.4 we have

\[ T_m \mathcal{E}_{N_0} = \sigma(m) \mathcal{E}_{N_0} \]

for all monic polynomials \( m \) in \( A \). This tells us that the function \( \mathcal{E}_{N_0} \), which is an analogue of Eisenstein series, generates a one-dimensional eigenspace for all Hecke operators. We point out that suppose \( N_0 = \prod_{\ell=1}^\ell P_i \), by comparing the Fourier coefficients one gets

\[ q^2 \mathcal{E}_{N_0}(g_\infty) = E(g_\infty) + \sum_{i=1}^\ell (-1)^i \sum_{1 \leq j_1 < \cdots < j_i \leq \ell} E\left( \begin{pmatrix} P_{j_1} & \cdots & P_{j_i} & 0 \\ 0 & 1 \end{pmatrix} g_\infty \right) \]

for \( g_\infty \in \text{GL}_2(k_\infty) \) where \( E \) is the improper Eisenstein series introduced in [9].

For each non-zero ideal \( N \) of \( A \), recall the Petersson inner product, which is a non-degenerate pairing on the finite dimensional \( \mathbb{C} \)-vector space \( S(\Gamma_0(N)) \) of automorphic cusp forms of Drinfeld type for \( \Gamma_0(N) \),

\[ (f, g) := \int_{G_0(N)} f \cdot \overline{g}. \]

Here \( G_0(N) = \Gamma_0(N) \backslash \text{GL}_2(k_\infty)/\Gamma_\infty k_\infty^\times \). The measure on \( G_0(N) \) is taken by counting the size of the stabilizer of an element (cf. [7] §4.8). More precisely, let \( \Gamma \) be a congruence subgroup and \( e \in \text{GL}_2(k_\infty)/\Gamma_\infty k_\infty^\times \). We denote \( \text{Stab}_\Gamma(e) \) the stabilizer of \( e \) in \( \Gamma \), which is a finite subgroup in \( \Gamma \). One takes the measure \( d([e]) \) of each double coset \([e]\) in \( \Gamma \backslash \text{GL}_2(k_\infty)/\Gamma_\infty k_\infty^\times \) where

\[ d([e]) := \frac{\#(Z(\Gamma))}{\#(\text{Stab}_\Gamma(e))}. \]

Here \( Z(\Gamma) \) is the subgroup of scalar matrices in \( \Gamma \). When \( \Gamma = \Gamma_0(N) \), for \( f \) and \( g \) in \( S(\Gamma_0(N)) \),

\[ (f, g) = \sum_{[e] \in G_0(N)} f(e) \overline{g(e)} d([e]). \]

**Definition 2.5.** An old form is a linear combinations of forms

\[ f' \left( \begin{pmatrix} d & 0 \\ 0 & 1 \end{pmatrix} g_\infty \right) \]

for \( g_\infty \in \text{GL}_2(k_\infty) \), where \( f' \) is an automorphic cusp form of Drinfeld type for \( \Gamma_0(M), M|N, M \neq N \), and \( \text{d}([N/M]) \). An automorphic cusp form \( f \) of Drinfeld type for \( \Gamma_0(N) \) is called a new form if for any old form \( f' \) one has

\[ (f, f') = 0. \]

If \( f \) is a new form which is also a Hecke eigenform, then \( f \) is called a newform.
It is known that the dimension of Drinfeld type cusp forms for $\Gamma_0(N_0)$ is equal to the genus of the Drinfeld modular curve $X_0(N_0)$ (cf. [7]). Let $S_{new}^{\text{new}}(\Gamma_0(N_0))$ be the space of new forms for $\Gamma_0(N_0)$ and $h_{N_0}$ be the number of left ideal classes of the maximal order $R$. As in the classical case, we can deduce that

$$h_{N_0} = \frac{1}{q^2 - 1} \prod_{P|N_0} (q^{\deg P} - 1) + \frac{q}{2(q + 1)} \prod_{P|N_0} (1 - (-1)^{\deg P}).$$

From the genus formula of $X_0(N_0)$ in [5], the dimension of $S_{new}^{\text{new}}(\Gamma_0(N_0))$ is equal to $h_{N_0} - 1$.

In the next subsection we will give our main theorem, which is essentially a construction of the space $S_{new}^{\text{new}}(\Gamma_0(N_0))$ of new forms for $\Gamma_0(N_0)$ via the theta series $\Theta_{ij}$.

### 2.3 Main theorem

Consider the definite Shimura curve $X = X_{N_0}$ introduced in §1. Recall the height pairing

$$<e, e'> = \sum_i a_i a'_i$$

where $e \in \text{Pic}(X)$ with $e = \sum_i a_i e_i$ and $e' \in \text{Pic}(X)^{\vee}$ with $e' = \sum_i a'_i \bar{e}_i$.

Let $M(\Gamma_0(N_0))$ be the space of automorphic forms of Drinfeld type for $\Gamma_0(N_0)$. Define $\Phi : \text{Pic}(X) \times \text{Pic}(X)^{\vee} \to M(\Gamma_0(N_0))$ by

$$\Phi(e, e') := q^2 \sum_{i,j} a_i a'_j \Theta_{ij}$$

for any $e \in \text{Pic}(X)$ with $e = \sum_i a_i e_i$ and $e' \in \text{Pic}(X)^{\vee}$ with $e' = \sum_i a'_i \bar{e}_i$. Then for $r \in \mathbb{Z}$ and $u \in k_\infty$ we have the following Fourier expansion

$$\Phi(e, e') \left( \begin{array}{cc} \pi_\infty^r & u \\ 0 & 1 \end{array} \right) = q^{-r+2} \left( \deg e \cdot \deg e' + \sum_{\substack{m \text{ monic}, \\ \deg m \leq r-2}} <e, t_m e'> \sum_{\epsilon \in F_q^*} \psi_\infty(\epsilon nu) \right).$$

Since

$$<t_m e, e'> = <e, t_m e'>$$

for any monic polynomial $m \in A$, by Proposition 2.4 one has

$$T_m(\Phi(e, e')) = \Phi(t_m e, e') = \Phi(e, t_m e').$$

In fact, the image of $\Phi$ is in $M_{new}(\Gamma_0(N_0)) := S_{new}^{\text{new}}(\Gamma_0(N_0)) \oplus \mathbb{C}E_{N_0}$. To see this, we need the following claim.

**Claim:** for any monic $m \in A$, consider $t_m$ as in $\text{End}(\text{Pic}(X))$ and restrict $T_m$ to the subspace $M_{new}(\Gamma_0(N_0))$. We have

$$\text{Tr} t_m = \text{Tr} T_m.$$
This claim tells us that the \( \mathbb{C} \)-algebra \( \mathcal{T}_\mathbb{C} \) generated by all \( t_m \) is isomorphic to the \( \mathbb{C} \)-algebra generated by all Hecke operators \( T_m \). Moreover, \( \text{Pic}(X) \otimes \mathbb{C} \) and \( M_{\text{new}}(\Gamma_0(N_0)) \) are isomorphic as \( \mathbb{T}_\mathbb{C} \)-modules.

According to multiplicity one theorem, which will be recalled in the Appendix \( \Delta A.2 \), \( M_{\text{new}}(\Gamma_0(N_0)) \) is a free rank one \( \mathbb{T}_\mathbb{C} \)-module. More precisely, \( M_{\text{new}}(\Gamma_0(N_0)) \) is generated by the element \( f \) whose Fourier coefficients are

\[
f^*(r, \lambda) = q^{-r+2} \cdot Tr(T_m)
\]

for all \( 0 \neq \lambda \in A \), \( (\lambda) = (m) \), \( \deg \lambda + 2 \leq r \). Therefore \( \text{Pic}(X) \otimes \mathbb{C} \) is also a free rank one \( \mathbb{T}_\mathbb{C} \)-module. This shows

\[
\dim_\mathbb{C} M_{\text{new}}(\Gamma_0(N_0)) = \dim_\mathbb{C} \left[ \left( \text{Pic}(X) \otimes \mathbb{C} \right) \otimes_{\mathbb{T}_\mathbb{C}} \left( \text{Pic}(X)^\vee \otimes \mathbb{C} \right) \right].
\]

Moreover, since

\[
\sum_{i=1}^n <e_i, t_m e_i> = Tr(B(m)) = Tr(t_m),
\]

we get \( \sum_{i=1}^n \Phi(e_i, \bar{e}_i) = f \), which generates \( M_{\text{new}}(\Gamma_0(N_0)) \). This also tells us that \( \sum_{i=1}^n e_i \otimes \bar{e}_i \) is a generator of the cyclic \( \mathbb{T}_\mathbb{C} \)-module \( \left( \text{Pic}(X) \otimes \mathbb{C} \right) \otimes_{\mathbb{T}_\mathbb{C}} \left( \text{Pic}(X)^\vee \otimes \mathbb{C} \right) \).

The above argument gives us the main result:

**Theorem 2.6.** There is a map \( \Phi : \text{Pic}(X) \times \text{Pic}(X)^\vee \rightarrow M_{\text{new}}(\Gamma_0(N_0)) \) satisfying that for \( r \in \mathbb{Z} \) and \( u \in k_\infty \)

\[
\Phi(e, e') \left( \frac{\pi_\infty^r}{0 \ 1} \right) \begin{pmatrix} u \\ 1 \end{pmatrix} = q^{-r+2} \left( \deg e \cdot \deg e' + \sum_{m \text{ monic}, \ \deg m \leq r-2} <e, t_m e'> + \sum_{(\lambda) = (m)} \psi_\infty(\lambda u) \right),
\]

and for all monic polynomials \( m \) in \( A \)

\[
T_m \Phi(e, e') = \Phi(t_m e, e') = \Phi(e, t_m e').
\]

Moreover, this map induces an isomorphism

\[
\left( \text{Pic}(X) \otimes \mathbb{C} \right) \otimes_{\mathbb{T}_\mathbb{C}} \left( \text{Pic}(X)^\vee \otimes \mathbb{C} \right) \cong M_{\text{new}}(\Gamma_0(N_0))
\]

as \( \mathbb{T}_\mathbb{C} \)-modules.

**Remark.** 1. When \( N_0 \) is a prime, \( M_{\text{new}}(\Gamma_0(N_0)) = M(\Gamma_0(N_0)) \) and so the theta series \( \Theta_{ij} \) gives us a construction of all automorphic forms of Drinfeld type for \( \Gamma_0(N_0) \). This case was proven by Papikian [10] via a geometric approach.

2. Since the theta series \( \Theta_{ij} \) are \( \mathbb{Q} \)-valued, the map \( \Phi \) in Theorem 2.6 in fact induces an isomorphism

\[
\left( \text{Pic}(X) \otimes \mathbb{Q} \right) \otimes_{\mathbb{T}_\mathbb{Q}} \left( \text{Pic}(X)^\vee \otimes \mathbb{Q} \right) \cong M_{\text{new}}(\Gamma_0(N_0), \mathbb{Q})
\]
where $T_0$ is the $\mathbb{Q}$-algebra generated by $t_m$ for all monic $m$ in $A$ and $M^{\text{new}}(\Gamma_0(N_0), \mathbb{Q})$ is the space of $\mathbb{Q}$-valued functions in $M^{\text{new}}(\Gamma_0(N_0))$.

3. The claim above is essentially the Jacquet-Langlands correspondence over the function field $k$, which will be recalled in the Appendix §A.1.

2.4 Example: The function $g_A$

Having Theorem 2.6, we exhibit automorphic forms of Drinfeld type with nice arithmetic properties. Let $D \in A - k_0^2$ be a square-free element with the quadratic Legendre symbol $\left( \frac{D}{p} \right) \neq 1$ for all $P \mid N_0$. Let $K$ be the imaginary quadratic field $k(\sqrt{D})$ and $O_K$ be the integral closure of $A$ in $K$. Recall that in §1.1 one has a free action of $\text{Pic}(O_K)$ on the set $G_D$ of Gross points of discriminant $D$ in the definite Shimura curve $X = X_{N_0}$:

$$G_D \times \text{Pic}(O_K) \rightarrow G_D \quad (x, A) \mapsto x_A.$$ 

Suppose a Gross point $x$ of discriminant $D$ in $X$ is given. For each ideal class $A$ in $\text{Pic}(O_K)$, denote $e_A$ to be the divisor class $(x_A)$ in $\text{Pic}(X)$. Define

$$g_A := \sum_{B \in \text{Pic}(O_K)} \Phi(e_B, e_A B).$$

We have a nice formula for the Fourier coefficients of $g_A$ in terms of Hecke actions: for monic $m \in A$ with $\deg m + 2 \leq r$,

$$g^*_A(r, m) = q^{-r+2} \sum_{B \in \text{Pic}(O_K)} < e_B, t_m e_A B >,$$

$$g^*_A(r, 0) = q^{-r+2} \cdot h_{O_K}.$$ 

Here $h_{O_K} = \# \text{Pic}(O_K)$. Note that $g_A$ is independent of the choice of the Gross point $x$.

From now on we assume $D$ is irreducible with $\left( \frac{D}{p} \right) = -1$ for all primes $P \mid N_0$. According to Dirichlet’s theorem there exists a monic irreducible polynomial $Q$ prime to $N_0$ and $\epsilon_0 \in \mathbb{F}_q^* - \mathbb{F}_q^2$ such that $\deg N_0 Q D$ is odd and $\epsilon_0 N_0 Q \equiv 1 \mod D$. Then there exists $j \in \mathbb{D}$ with $j^2 = \epsilon_0 N_0 Q$ so that $D = K + K j$ and $j^{-1} a j = \bar{a}$ for $a \in K$.

Let $d = (\sqrt{D})$ be the different of $O_K$, which is a prime ideal in $O_K$. Since $\epsilon_0 N_0 Q \equiv 1 \mod D$, one has $\left( \frac{\epsilon N_0 Q D}{d} \right) = 1$. From the reciprocity law we get $\left( \frac{D}{Q} \right) = 1$ and so the prime ideal $(Q)$ is split in $K$. Suppose $(Q) = q q$ and set

$$R := \{ \alpha + \beta j : \alpha \in d^{-1}, \beta \in d^{-1} q^{-1}, \alpha - \beta \in O_0 \}.$$
Here $O_\mathfrak{d}$ is the localization of $O_K$ at $\mathfrak{d}$. It is clear that $R$ is an $A$-lattice in $\mathcal{D}$ containing 1. In fact, $R$ is a maximal $A$-order and $K \cap R = O_K$. To show $R$ is an $A$-order, let $\alpha_1 + \beta_1j$ and $\alpha_2 + \beta_2j$ be two elements in $R$. Then
\[(\alpha_1 + \beta_1j)(\alpha_2 + \beta_2j) = (\alpha_1\alpha_2 + \beta_1\beta_2\epsilon_0N_0Q) + (\alpha_1\beta_2 + \beta_1\alpha_2)j.\]

For $i = 1, 2$, write $\beta_i$ as $\alpha_i + \delta_i$ with $\delta_i \in O_\mathfrak{d}$. Then
\[\alpha_1\alpha_2 + \beta_1\bar{\beta}_2\epsilon_0N_0Q = \alpha_1(\alpha_2 + \bar{\alpha}_2) + (\delta_1\bar{\beta}_2 + \beta_1\bar{\delta}_2 + \delta_1\delta_2)\epsilon_0N_0Q.\]

Since $\alpha_2 \in \mathfrak{d}^{-1} = A + \sqrt{D}^{-1}A$, one has
\[\alpha_2 + \bar{\alpha}_2 \in A.\]

Hence
\[\alpha_1\alpha_2 + \beta_1\bar{\beta}_2\epsilon_0N_0Q \in \mathfrak{d}^{-2} \cap \sqrt{D}^{-1}O_\mathfrak{d} = \mathfrak{d}^{-1}.\]

Similarly,
\[\alpha_1\beta_2 + \beta_1\bar{\alpha}_2 \in \mathfrak{d}^{-2q^{-1}} \cap \sqrt{D}^{-1}O_\mathfrak{d} = \mathfrak{d}^{-1}q^{-1}.\]

From the condition that $\epsilon_0N_0Q \equiv 1 \mod D$, one can check that
\[\alpha_1\alpha_2 + \beta_1\bar{\beta}_2\epsilon_0N_0Q = (\alpha_1\beta_2 + \beta_1\bar{\alpha}_2) \in O_\mathfrak{d}.\]

Therefore $R$ is an $A$-order. The discriminant of $R$ is $(N_0)^2$, which can be checked locally. This implies that $R$ is maximal.

Let $x$ be the Gross point in the definite Shimura curve $X = X_{N_0}$ which corresponds to the trivial ideal $R$ and the embedding $K \hookrightarrow \mathcal{D}$. Then $x$ is of discriminant $D$. Using this particular Gross point we can get an explicit formula for the Fourier coefficients of $g_A$.

Note that there is a one-to-one correspondence between the irreducible components of $X$ and the left ideal classes of $R$. Let $a \in A$, $b \in \mathcal{B}$. Then $Ra$ and $Rb$ are representatives of the left ideal classes of $R$ corresponding to $e_A$ and $e_{AB}$ respectively. Therefore
\[< e_\mathcal{B}, t_me_{AB} >= \frac{1}{q-1}\{ b \in b^{-1}Rba : (\text{Nr}(b))/\text{Nr}(a) = (m) \}.\]

Assume $N_0\mathfrak{d}$ and $a$ are relatively prime. Then
\[b^{-1}Rba = \{ \alpha + \beta j : \alpha \in \mathfrak{d}^{-1}a, \beta \in \mathfrak{d}^{-1}b^{-1}q^{-1}\bar{a}, \alpha = (-1)^{\text{ord}_\mathfrak{d}(b)}\beta \in O_\mathfrak{d} \}.\]

We can express the Fourier coefficients of $g_A$ in terms of sums of the counting numbers
\[r_A((\lambda)) := \#\{a \in A : a \text{ integral with } \text{Nr}(a) = (\lambda) \},\]
for ideals $(\lambda)$ of $A$, by the following proposition:
Proposition 2.7. Suppose $D \in A - k^2_\infty$ is irreducible with $(D/P) = -1$ for all primes $P \mid N_0$. Then for any monic polynomial $m$ in $A$,

$$
\sum_{B \in \text{Pic}(O_K)} <e_B, t_me_A B> = \frac{1}{2(q-1)} \left[ 2r_A((mD))(q-1)h \right] + \sum_{\substack{\mu \in A, \mu \neq 0 \in \hat{h} \in \deg(\mu N_0) \leq \deg(mD) \mu}} r_A((\mu N_0 - mD))(m) + 1(1 - \delta_{\mu N_0}(\mu N_0 - mD)) \sum_{c|\mu} \left( \frac{D}{c} \right).
$$

Here $t(\mu, D) = 1$ if $D$ divides $\mu$ and 0 otherwise, and $\delta_z$ is the norm residue symbol of $z$ for $z \in k_\infty^\times$; $\delta_z = 1$ if $z \in \text{Pic}(K_\infty)$ and $\delta_z$ otherwise.

Proof. Let $a \in A$ which is a proper ideal of $O_K$ and prime to $N_0\hat{a}$. Fix a generator $\lambda_0$ of $\text{Nr}(a) = a\hat{a}$. Given $B \in \text{Pic}(O_K)$. Let $b \in B$. For $b = \alpha + \beta j \in b^{-1}R\bar{b} a$, i.e. $\alpha \in d^{-1}a$, $\beta \in d^{-1}q^{-1}b^{-1}b a$, $\alpha = (-1)^\text{ord}_a b \beta \in O_0$, define:

1. $c := (\beta)d\bar{a}^{-1}b \in [a]B^2A$,
2. $\nu := -\text{Nr}(a)D\lambda_0^{-1} \in A$,
3. $\mu := -\epsilon_0 \text{Nr}(\beta)DQ\lambda_0^{-1} \in A$.

Here $[a] \in \text{Pic}(O_K)$ is the ideal class containing $a$. Then $c$ is integral and

$$
\text{Nr}(\alpha + \beta j) = \text{Nr}(\alpha) - \epsilon_0 N_0Q \text{Nr}(\beta) = (-\nu + N_0\mu)D^{-1}\lambda_0.
$$

Thus $(\text{Nr}(\alpha + \beta j)) = (m\lambda_0)$ if and only if $\nu = N_0\mu - cmD$ for a uniquely determined $c \in F_q^\times$.

Since $\beta = 0$ if and only if $b = \alpha \in a$, one has

$$
\#\{b \in b^{-1}R\bar{b}a : \text{Nr}(b) = (m\lambda_0)\} = \#\{b = \alpha + \beta j \in b^{-1}R\bar{b}a : \beta \neq 0, \text{Nr}(b) = (m\lambda_0)\} + \#\{\alpha \in a : \text{Nr}(\alpha) = (m\lambda_0)\}.
$$

It can be shown that $\#\{\alpha \in a : \text{Nr}(\alpha) = (m\lambda_0)\} = (q - 1)r_A((mD))$. Note that $\beta \neq 0$ if and only if $\mu \neq 0$. In this case, $\beta$ is uniquely determined by the integral ideal $c$ up to multiplying elements in $O_K^\times$.

Conversely, given $0 \neq \mu \in A$ and $c \in F_q^\times$ and set $\nu = N_0\mu - cmD$. The number of elements $\alpha \in d^{-1}a$ with $\text{Nr}(\alpha) = -\nu D^{-1}\lambda_0$ is $r_{\alpha, \lambda_0}(N_0\mu - cmD)$. Here

$$
r_{\alpha, \lambda_0}(\lambda) := \#\{\alpha \in a : \text{Nr}(\alpha) = \lambda\lambda_0\} \text{ for } \lambda \in A.
$$

In the case of $r_{\alpha, \lambda_0}(N_0\mu - cmD) \neq 0$, choose an element $\alpha \in d^{-1}a$ with $\text{Nr}(\alpha) = -\nu D^{-1}\lambda_0$. Let $c$ be an integral ideal which lies in a class differing from the ideal class $A[q]$ by a square $b^{-1}b a^{-1}$ in the class group $\text{Pic}(O_K)$ and with ideal norm $(\mu)$. Then

$$
c \cdot b^{-1}b a^{-1}d^{-1} = (\beta)
for some $\beta \in K^\times$. Suppose we can find $\beta$ so that $\mu = -\epsilon_0 \operatorname{Nr}(\beta) D Q \lambda_0^{-1} \in A$.
Since $\epsilon_0 N_0 Q \equiv 1 \mod D$, the equality $e m \lambda_0 = \operatorname{Nr}(\alpha) - \epsilon_0 N_0 Q \operatorname{Nr}(\beta) \in A$ implies
\[
\alpha \pm \beta \in O_0.
\]
Choose $\ell \in \{0, 1\}$ and replace $b$ by $b \delta^\ell$ so that $\alpha - (-1)^{\operatorname{ord}_c(b)} \beta \in O_0$. Therefore $b = \alpha + \beta j \in b^{-1} R b a$ with $\operatorname{Nr}(b) = e m \lambda_0$. Note that if $\beta$ is not in $O_0$ (i.e. $D \nmid \mu$), then $\ell$ is uniquely determined. If $\beta \in O_0$ (i.e. $D \mid \mu$), then we have two choices $\pm \beta$. The existence of $\beta$ is equivalent to that $-\epsilon_0^{-1} D \mu Q^{-1} \lambda_0$ is in $\operatorname{Nr}(K^\times)$. Since $\operatorname{Nr}(\sqrt{D}) = -D$ and $(\epsilon_0^{-1} \mu Q^{-1} \lambda_0) = \operatorname{Nr}(\epsilon q^{-1} a)$, we have $\epsilon_0^{-1} \mu Q^{-1} \lambda_0 \in \operatorname{Nr}(K^\times)$ if and only if $\delta_0^{-1} \mu Q^{-1} \lambda_0 = 1$. Therefore combining the above arguments we have
\[
\sum_{b \in \operatorname{Pic}(O_K)} \# \{ b = \alpha + \beta j \in b^{-1} R b a : \beta \neq 0, \operatorname{Nr}(b) = (m \lambda_0) \}
= \sum_{\mu \neq A, c \in \mathbb{F}_q^\times} r_{a, \lambda_0} (N_0 \mu - e m D)(t(\mu, D) + 1) \cdot \frac{1 + \delta_0^{-1} \mu Q^{-1} \lambda_0}{2}.
\]
Here $\mathcal{R}_{\{A[\mu]\}}((\mu))$ is the number of integral ideals $c$, which lie in a class differing from the class $A[\mu]$ by a square in the class group $\operatorname{Pic}(O_K)$ and with ideal norm $(\mu)$. Following the proof of Lemma 3.4.9 in [12] one has

**Lemma 2.8.** For $0 \neq \mu \in A$,
\[
\mathcal{R}_{\{A[\mu]\}}((\mu)) \cdot \frac{1 + \delta_0^{-1} \mu Q^{-1} \lambda_0}{2} = \frac{1}{q - 1} \sum_{c | \mu} \left( \frac{D}{c} \right) \cdot \frac{1 + \delta_0^{-1} \mu Q^{-1} \lambda_0}{2}.
\]

Since $\delta_0^{-1} \mu Q^{-1} \lambda_0 = 1$ if and only if $\delta N_0 \mu \lambda_0 = -1$, with Lemma 2.6 we have
\[
\sum_{b \in \operatorname{Pic}(O_K)} \# \{ b = \alpha + \beta j \in b^{-1} R b a : \beta \neq 0, \operatorname{Nr}(b) = (m \lambda_0) \}
= \sum_{\mu \neq A, c \in \mathbb{F}_q^\times} r_{a, \lambda_0} (N_0 \mu - e m D)(t(\mu, D) + 1) \cdot \frac{1 - \delta N_0 \mu \lambda_0}{2} \cdot \frac{1}{q - 1} \sum_{c | \mu} \left( \frac{D}{c} \right)
= \sum_{\mu \neq A, c \in \mathbb{F}_q^\times} r_A((\mu N_0 - m D))(t(\mu, D) + 1) \cdot \frac{1 - \delta \mu N_0 (\mu N_0 - m D)}{2} \cdot \sum_{c | \mu} \left( \frac{D}{c} \right).
\]

Therefore
\[
\sum_{b \in \operatorname{Pic}(O_K)} < e_B, t_m e_A b > = \frac{1}{2(q - 1)} \left[ 2 r_A((m D))(q - 1) h_{O_K} \right.
+ \sum_{\mu \neq A, c \in \mathbb{F}_q^\times} r_A((\mu N_0 - m D))(t(\mu, D) + 1)(1 - \delta \mu N_0 (\mu N_0 - m D)) \sum_{c | \mu} \left( \frac{D}{c} \right).
\]

\[\square\]
3 Special values of $L$-series

3.1 Rankin product

To an automorphic cusp form $f$ of Drinfeld type for $\Gamma_0(N)$ one can attach an $L$-series $L(f, s)$: let $m$ be an effective divisor of $k$, which can be written as $\text{div}(\lambda)_0 + (r - \deg \lambda)\infty$ for a nonzero polynomial $\lambda (= \lambda(m))$ in $A$, with

$$\text{div}(\lambda)_0 := \sum_{\text{finite prime } P} \text{ord}_P(\lambda)P.$$

Denote

$$f^*(m) := \int_{A\backslash k^{\infty}} f \left( \frac{\pi}{\infty} u \right) \psi_{\infty}(-\lambda u)du = f^*(r + 2, \lambda).$$

The $L$-series $L(f, s)$ attached to $f$ is

$$L(f, s) := \sum_{m \geq 0} f^*(m)q^{-\deg(m)s}, \quad \text{Re } s > 1.$$

Let $D \in A - k_\infty^2$ be a square-free element. Consider the imaginary field $K = k(\sqrt{D})$. Let $O_K$ be the integral closure of $A$ in $K$ and Pic($O_K$) be the ideal class group of $O_K$. Given an ideal class $A \in \text{Pic}(O_K)$ and a polynomial $\lambda$ in $A$. The number of integral ideals $a$ in the class $A$ with $N_{K/k}(a) = (\lambda)$ leads to the partial zeta function attached to $A$:

$$\zeta_A(s) := \sum_{m \geq 0} r_A(m)q^{-\deg(m)s}, \quad \text{Re } s > 1.$$

Here for each effective divisor $m = \text{div}(\lambda)_0 + (r - \deg \lambda)\infty$,

$$r_A(m) := \# \{a \in A : a \text{ integral with } N_{K/k}(a) = (\lambda) \}.$$

Let $f$ be an automorphic cusp form of Drinfeld type for $\Gamma_0(N)$. For each ideal class $A \in \text{Pic}(O_K)$, we are interested in the Rankin product:

$$L(f, A, s) := \sum_{m \geq 0} f^*(m)r_A(m)q^{-\deg(m)s}, \quad \text{Re } s > 1.$$

To study the analytic continuation and the functional equation of $L(f, A, s)$, consider the function $\Lambda(f, A, s)$ which is defined by:

$$\Lambda(f, A, s) := \begin{cases} L^{(N,D)}(2s + 1)L(f, A, s) & \text{when deg } D \text{ is odd}, \\ \frac{1}{1 + q^{s-1}}L^{(N,D)}(2s + 1)L(f, A, s) & \text{when deg } D \text{ is even}. \end{cases}$$
Here $L^{(N,D)}(s)$ is the following $L$-series indexed by effective divisors supported outside $\infty$

$$L^{(N,D)}(s) := \frac{1}{q-1} \sum_{d \in A,(d,N)=1} \left( \frac{D}{d} \right) q^{-s \deg d}, \quad \text{Re}(s) > 1,$$

where $\left( \frac{D}{a} \right)$ denotes the Legendre symbol for the polynomial ring $A$. Note that

$$L^{(N,D)}(s) = L_D(s) \cdot \prod_{\text{prime ideals } P | N} (1 - \left( \frac{D}{P} \right) q^{-s \deg P})^{-1}$$

where $L_D(s)$ is the Dirichlet $L$-series:

$$L_D(s) := \frac{1}{q-1} \sum_{d \in A,d \neq 0} \left( \frac{D}{d} \right) q^{-s \deg d}, \quad \text{Re}(s) > 1.$$ 

It is known that $L_D(s)$ can be extended to a polynomial in $q^{-s}$ with the functional equation (cf. [1]):

$$L_D(2s + 1) = q^{s(-2 \deg D + 2) - \frac{1}{2} \deg D + \frac{1}{2}} L_D(-2s)$$

if $\deg D$ is odd, and

$$L_D(-2s + 1) = \frac{1 + q^{1-2s}}{1 + q^{2s}} q^{\deg D(2s - \frac{1}{2})} L_D(2s)$$

if $\deg D$ is even.

When $f$ is a new form and $D$ is irreducible, Rück and Tipp ([12]) prove the following functional equation of $\Lambda(f,A,s)$:

$$\Lambda(f,A,s) = - \left( \frac{D}{N} \right) q^{(5-2 \deg D - 2 \deg N) s} \Lambda(f,A,-s)$$

when $\deg D$ is odd, and

$$\Lambda(f,A,s) = - \left( \frac{D}{N} \right) q^{(6-2 \deg D - 2 \deg N) s} \Lambda(f,A,-s)$$

when $\deg D$ is even.

### 3.2 Central critical values of $\Lambda(f,A,s)$

We are interested in the special value of $\Lambda(f,A,s)$ at $s = 0$. Note that if $\left( \frac{D}{N} \right) = 1$, then $\Lambda(f,A,s)$ has a zero at $s = 0$. We focus here on the special case when $\left( \frac{D}{P} \right) = -1$ for all primes $P | N_0$. Adapting Rankin’s method (cf. [12]), we can establish the following theorem.
THEOREM 3.1. Let $f$ be a Drinfeld type new form for $\Gamma_0(N_0)$ and let $D$ be an irreducible polynomial in $A - k_\infty^2$ with $(\frac{D}{P}) = -1$ for all primes $P \mid N_0$. One has

$$\Lambda(f, A, 0) = \begin{cases} \frac{(f, g_A)}{q^{\frac{1}{2}(\deg D + 1)}} & \text{when } \deg D \text{ is odd}, \\ \frac{(f, g_A)}{2q^{\frac{1}{2}\deg D}} & \text{when } \deg D \text{ is even.} \end{cases}$$

Here $(\cdot, \cdot)$ is the Petersson inner product and $g_A$ is the Drinfeld type automorphic form for $\Gamma_0(N_0)$ canonically attached to $A$ in §2.4.

3.2.1 Review of Rankin’s method

Given $A \in \text{Pic}(O_K)$. Choose $a_0 \in A^{-1}$ and $\lambda_0 \in k$ such that $N_{K/k}(a_0) = (\lambda_0)$.

Recall the counting number

$$r_{a_0, \lambda_0}(\lambda) = \# \{ \mu \in a_0 : N_{K/k}(\mu) = \lambda_0 \lambda \}.$$ 

Note that $r_{a_0, \lambda_0}(\lambda) = r_{a_0^{-1}, \lambda_0^{-1}}(\lambda)$, and for effective divisor $m = \text{div}(\lambda_0) + (\deg m - \deg \lambda)\infty$ we have

$$r_A(m) = \frac{1}{q - 1} \sum_{\epsilon \in \mathbb{F}_q^*} r_{a_0, \lambda_0}(\epsilon \lambda).$$

We consider the following theta series $\theta_{a_0, \lambda_0}$ (introduced in [11]) defined on $k_\infty \times k_\infty$:

$$\theta_{a_0, \lambda_0}(\pi_\infty^r, u) := \sum_{\deg \lambda + 2 \leq r} r_{a_0, \lambda_0}(\lambda) \psi_{\infty}(\lambda u).$$

It satisfies the following transformation law:

$$\theta_{a_0, \lambda_0}\left(\frac{\pi_\infty^r}{(cu + d)^2}, \frac{au + b}{cu + d}\right) = \delta_{cu+d} \left(\frac{d}{D}\right) q^{-v_\infty(\epsilon u_d)} \theta_{a_0, \lambda_0}(\pi_\infty^r, u)$$

for all $\gamma = \left(\begin{array}{cc} a & b \\ c & d \end{array}\right) \in \Gamma_0^{(1)}(N) := \Gamma_0(N) \cap \text{SL}_2(A)$ with $v_\infty(\epsilon u_d) > v_\infty(\epsilon u_d)$.

Here $\delta$ is the local norm symbol at $\infty$, i.e. $\delta_z = 1$ if $z \in k_\infty^\times$ is a norm of an element in $K_\infty = k_\infty(\sqrt{D})$ and $-1$ otherwise.

Viewing $\theta_{a_0, \lambda_0}$ as a function on

$$\mathbb{H}_\infty := \left(\begin{array}{cc} 1 & A \\ 0 & 1 \end{array}\right) \backslash \left(\begin{array}{cc} k_\infty^\times & k_\infty \\ 0 & 1 \end{array}\right) / \left(\begin{array}{cc} O_\infty^\times & O_\infty \\ 0 & 1 \end{array}\right),$$

one can write

$$L(f, A, s) = \frac{q}{q - 1} \sum_{r = 2}^{\infty} \left[ \sum_{u \in \pi_\infty O_\infty / \pi_\infty^2 O_\infty} f \cdot \theta_{a_0, \lambda_0}(\pi_\infty^r, 0) u^{-(s+1)+2s} \right] \left[ f(h) \theta_{a_0, \lambda_0}(h) q^{-r(s+1)+2s} dh \right].$$

$$= \frac{q}{q - 1} \int_{\mathbb{H}_\infty} f(h) \theta_{a_0, \lambda_0}(h) q^{-r(s+1)+2s} dh.$$
For every monic polynomial $M$ in $A$, the canonical map
\[ \mathbb{H}_\infty \longrightarrow G(M) := \Gamma^{(1)}_0(M) \setminus \text{GL}_2(k_\infty)/\Gamma_\infty k_\infty^\times \]
is surjective. Following [12], we consider the “Eisenstein series”
\[ E_s \left( \begin{array}{cc} \pi_r \infty & u  \\ 0 & 1 \end{array} \right) := \sum_{c,d \in A, c \equiv 0 \mod D, v_\infty(c \pi_r \infty + d) > v_\infty(cu + d)} \left( \frac{d}{D} \right) \delta_{cu+d} q^{v_\infty(cu+d)(2s+1)} \]
and let
\[ H_s \left( \begin{array}{cc} \pi_r \infty & u  \\ 0 & 1 \end{array} \right) := \begin{cases} q^{-r(s+1)+2s} E_s \left( \begin{array}{cc} N \pi_r \infty & Nu  \\ 0 & 1 \end{array} \right) & \text{when } \deg D \text{ is odd,} \\ \left( \frac{-1}{2} \right)^{-d \pi_0 \lambda_0 + 1} q^{-r(s+1)+2s} E_s \left( \begin{array}{cc} N \pi_r \infty & Nu  \\ 0 & 1 \end{array} \right) & \text{when } \deg D \text{ is even.} \end{cases} \]
Then $\theta_{a_0, \lambda_0} H_s$ can be viewed as a function on $G(ND)$. By [12] Proposition 2.2.2 and Proposition 2.3.2
\[ \Lambda(f, A, s) = \frac{q}{2(q-1)} \int_{G(ND)} f \cdot \theta_{a_0, \lambda_0} H_s. \]
Given $M \in A$. Let $\mathcal{F}(M)$ be the space of functions on $G(M)$. The trace map from $\mathcal{F}(ND)$ to $\mathcal{F}(N)$ is given by
\[ f \longrightarrow Tr^{ND}_{N} f(g) := \sum_{\gamma \in \Gamma^{(1)}_0(ND) \setminus \Gamma^{(1)}_0(N)} f(\gamma g). \]
Set $\Phi_s := Tr^{ND}_{N}(\theta_{a_0, \lambda_0} H_s)$. Then
\[ \Lambda(f, A, s) = \frac{q}{2(q-1)} \int_{G(N)} f \cdot \Phi_s. \]
From the harmonicity of $f$ one has
\[ \Lambda(f, A, s) = \frac{q}{4(q-1)} \int_{G(N)} f \cdot F_s \]
where for $g \in \text{GL}_2(k_\infty),$
\[ F_s(g) := \frac{q}{q+1} (\Phi_s(g) - \Phi_s(g)) + \frac{1}{q+1} \sum_{\beta \in \text{GL}_2(k_\infty)/\Gamma_\infty} (\Phi_s(g \beta) - \Phi_s(g \beta)). \]
Note that $F_s$ depends on the choice of $a_0$ and $\lambda_0$. 
3.2.2 Proof of Theorem 3.1

Let $\Psi$ be the average map from functions $F$ on $G(N)$ to functions on $G_0(N)$:

$$\Psi(F)(g) := \frac{1}{q-1} \sum_{\epsilon \in \mathbb{F}_q^\times} F(\begin{pmatrix} \epsilon & 0 \\ 0 & 1 \end{pmatrix} g).$$

Define

$$\Psi_A := \Psi(F_0).$$

Note that $\Psi_A$ now depends only on $A$.

Taking the formulas in Proposition 2.7.2 and Proposition 2.7.5 in [12] and specializing at $s = 0$ we deduce that for any $\lambda \in A$ with $\deg \lambda + 2 \leq r$

$$\Psi_A^*(r, \lambda) = \frac{3 - (-1)^{\deg D}}{4} \cdot q^{r + 1 - \frac{\deg D}{2}} \cdot \left[ 2r_A((\lambda D))(q-1) L_D(0) \right] + \sum_{d \in \mathbb{A}, d \neq 0, d \leq \deg(\lambda D)} r_A((\mu N - \lambda D)) (t(\mu, D) + 1)(1 - \delta_{\mu N(\mu N - \lambda D)}) \sum_{c|\mu} \left( \frac{D}{c} \right) \sum_{c|\mu} \left( \frac{D}{c} \right).$$

Moreover, one has

**Proposition 3.2.**

$$\Lambda(f, \chi, 0) = \frac{q}{2(q-1)} \int_{G_0(N)} f \cdot \Psi_A.$$ 

Let $N = N_0$. Note that $L_D(0) = h_{O_K}$. Comparing the Fourier coefficients of $\Psi_A$ with that of $g_A$ we obtain

$$\Psi_A = g_A \cdot \left\{ \begin{array}{ll} q^{-\frac{1}{2} \deg D + \frac{1}{2}} \cdot q^{2 - \deg D} \cdot (q-1) \cdot 2 & \text{when } \deg D \text{ is odd}, \\
 q^{-1} \cdot q^{-\frac{1}{2} \deg D} \cdot (q-1) & \text{when } \deg D \text{ is even}. \end{array} \right.$$ 

Therefore Theorem 3.1 holds. \( \Box \)

3.3 A function field analogue of Gross formula

Now given a character $\chi : \text{Pic}(O_K) \to \mathbb{C}^\times$, define

$$\Lambda(f, \chi, s) := \sum_{A \in \text{Pic}(O_K)} \chi(A) \Lambda(f, A, s).$$

When $\chi$ is the trivial character and $f$ is a newform which is “normalized” so that the Fourier coefficient $f^*(0) = 1$, one has

$$\Lambda(f, \chi, s) = L(f, s) L(f \otimes \varepsilon_D, s).$$
where \( \varepsilon_D \) is the following quadratic character on divisors of \( k \):

\[
\varepsilon_D(P) = \left( \frac{D}{P} \right) \quad \text{and} \quad \varepsilon_D(\infty) = \begin{cases} 
-1 & \text{if } \deg D \text{ is even,} \\
0 & \text{if } \deg D \text{ is odd;}
\end{cases}
\]

and \( L(f \otimes \varepsilon_D, s) \) is the twisted \( L \)-series of \( f \) by \( \varepsilon_D \):

\[
L(f \otimes \varepsilon_D, s) := \sum_{m \geq 0} f^*(m) \varepsilon_D(m) q^{-\deg m s}.
\]

From the definition of \( \Lambda(f, \chi, s) \) and Theorem 3.1 one has

\[
\Lambda(f, \chi, 0) = \left( \sum_{A \in \text{Pic}(O_K)} \chi(A)(f, g_A) \right) \cdot \begin{cases} 
\frac{1}{2q^{\frac{1}{2}(\deg D+1)}} & \text{if } \deg D \text{ is odd,} \\
\frac{1}{2q^{\frac{1}{2}\deg D}} & \text{if } \deg D \text{ is even.}
\end{cases}
\]

Note that

\[
\sum_{A \in \text{Pic}(O_K)} \chi(A)^{-1} g_A = \sum_{A \in \text{Pic}(O_K)} \left( \sum_{B \in \text{Pic}(O_K)} \chi(A)^{-1} \Phi(e_B, e_{AB}) \right)
\]

where \( \Phi \) is the map in Theorem 2.6 and

\[
e_\chi = \sum_{A \in \text{Pic}(O_K)} \chi(A) e_A.
\]

Suppose \( f \) is a normalized newform. Then from Theorem 2.6 \( f \) corresponds to a particular element \( e_f \in \text{Pic}(X) \otimes \mathbb{Z} \mathbb{R} \) such that

\[
f = \Phi(e_f, e_f).
\]

Let \( e_{f, \chi} \) be the projection of \( e_\chi \) to the \( e_f \)-isotypical component in the space \( \text{Pic}(X) \otimes \mathbb{Z} \mathbb{C} \) with respect to the Gross height pairing. Then the \( f \)-eigencomponent of \( \Phi(e_\chi, e_\chi) \) is equal to

\[
\Phi(e_{f, \chi}, e_\chi) = \Phi(e_{f, \chi}, e_{f, \chi}) = \langle e_{f, \chi}, e_{f, \chi} \rangle > f.
\]

The last equality holds as \( f \) is normalized (i.e. \( f^*(0) = 1 \)) and the Fourier coefficient \( \Phi(e_{f, \chi}, e_\chi)^* (0) = \langle e_{f, \chi}, e_{f, \chi} \rangle > f \). Therefore we obtain

**Theorem 3.3.** Let \( f \) be an automorphic cusp form of Drinfeld type for \( \Gamma_0(N_0) \) which is also a normalized newform. Then

\[
\Lambda(f, \chi, 0) = \begin{cases} 
\frac{(f, f)}{2q^{\frac{1}{2}(\deg D+1)}} \cdot \langle e_{f, \chi}, e_{f, \chi} \rangle & \text{if } \deg D \text{ is odd,} \\
\frac{(f, f)}{2q^{\frac{1}{2}\deg D}} \cdot \langle e_{f, \chi}, e_{f, \chi} \rangle & \text{if } \deg D \text{ is even.}
\end{cases}
\]
Remark. 1. If $\chi$ is non-trivial, then $\deg e_\chi = 0$ and so $\Phi(e_\chi, e_\chi)$ is a cusp form.
2. When $\chi$ is trivial, then
$$\sum_{\text{monic } m|N_0} t_m e_\chi = 2e_D$$
where $e_D$ is the divisor class introduced in Proposition 1.7.
3. The special case when $N_0$ is a prime and $\deg D$ is odd, the above formula coincides with the result in [10] §4 (be aware of the different choices of measures for the Petersson inner product).
4. When irreducible $D \in A - k_\infty^2$ satisfies $\left( \frac{D}{N_0^2} \right) = 1$, the derivative of $\Lambda(f, \chi, s)$ at $s = 0$ is given by Néron-Tate height of Heegner points on the Drinfeld modular curve $X_0(N_0)$, and an analogue of Gross-Zagier formula has been proved by Rück and Tipp in the case $D$ is irreducible (cf. [12]).

3.4 Example and application to elliptic curves

Let $E$ be a non-iso-trivial elliptic curve over $k$ (i.e. $E$ is not defined over the constant field $\mathbb{F}_q$). From the work of Weil, Jacquet-Langlands, and Deligne, one knows that there exists an automorphic cusp form $f_E$ such that
$$L(E/k, s + 1) = L(f_E, s).$$
Here $L(E/k, s)$ is the Hasse-Weil $L$-series of $E$ over $k$. Suppose the conductor of $E$ is $N_0\infty$, and $E$ has split multiplicative reduction at $\infty$. Then the automorphic form $f_E$ is of Drinfeld type for $\Gamma_0(N_0)$, which is a normalized newform (cf. [7]).

Consider the Hasse-Weil $L$-series $L(E/K, s)$ of $E$ over the imaginary quadratic field $K = k(\sqrt{D})$ where $D \in A$ with $\left( \frac{D}{P^2} \right) = -1$ for all primes $P | N_0$. One has
$$L(E/K, s + 1) = L(f_E, s)L(f_E \otimes \varepsilon_D, s)$$
where $L(f_E, s)$ is the twisted $L$-series of $f_E$ by the quadratic character $\varepsilon_D$. Since
$$L(f_E, s)L(f_E \otimes \varepsilon_D, s) = \Lambda(f_E, 1_D, s)$$
where $1_D$ is the trivial character on $\text{Pic}(O_K)$, from Theorem 3.3 we obtain a formula for the special value of $L(E/K, s)$ at $s = 1$ when $D$ is irreducible.

Now, let $k = \mathbb{F}_3(t)$ (i.e. $q = 3$). Let $E$ be the following elliptic curve over $k$:
$$E : y^2 = x^3 + (t^2 + 1)x^2 + t^2x = x(x + 1)(x + t^2).$$
The conductor of $E$ is $(t)(t + 1)(t - 1)\infty$. More precisely, $E$ has split multiplicative reduction at $(t)$ and $\infty$, and has non-split multiplicative reduction at $(t + 1)$ and $(t - 1)$. Let $N_0 = t(t + 1)(t - 1) = t^3 - t$. Let $f_E$ be the normalized
Drinfeld type cusp form for $\Gamma(N_0)$ associated to $E$. Since the $L$-series $L(E/k, s)$ of $E$ over $k$ is a polynomial in $q^{-s}$ of degree $(\deg N_0 + 1) - 4$ with constant term 1, this implies that $L(E/k, s) = L(f_E, s - 1) = 1$.

Let $D = t^3 - t - 1$ and $K = k(\sqrt{D})$. Then

$$\left( \frac{D}{t} \right) = \left( \frac{D}{t+1} \right) = \left( \frac{D}{t-1} \right) = -1.$$ 

The twist $E_D$ of $E$ by $D$ is the following elliptic curve over $k$:

$$y^2 = x^3 + (t^2 + 1)Dx^2 + t^2D^2x.$$ 

The conductor of $E_D$ is $(D)^2(t)(t+1)(t-1)\infty^2$, and the $L$-series $L(E_D/k, s)$ is

$$1 + q^{-s} + 4q^{-2s} + 108q^{-5s} + 243q^{-6s} + 2187q^{-7s}.$$ 

Since $L(E/K, s) = L(E/k, s) \cdot L(E_D/k, s)$, we have

$$L(E/K, s) = 1 + q^{-s} + 4q^{-2s} + 108q^{-5s} + 243q^{-6s} + 2187q^{-7s}$$

and $L(E/K, 1) = \frac{32}{7}$.

On the other hand, from a formula of Gekeler (cf. [13] Theorem 1.1) we immediately get

$$(f_E, f_E) = 32.$$ 

We point out that our choice of the measure is twice of the one in [13]. Such computation can be also checked via the algorithm in [15].

The only remaining term is the Gross height of the corresponding point $e_{f_E}$ in $\text{Pic}(X_{N_0}) \otimes \mathbb{Q}$. Let $\mathcal{D}$ be the definite quaternion algebra over $k$ ramified at $(t), (t + 1)$, and $(t - 1)$. Then

$$\mathcal{D} = k + k\alpha + k\beta + k\alpha\beta$$

where $\alpha^2 = -1$, $\beta^2 = N_0 = t^3 - t$, and $\beta\alpha = -\alpha\beta$. Let $R = A + A\alpha + A\beta + A\alpha\beta$, which is a maximal order in $\mathcal{D}$. The cardinality of $R^\times$ is 8, and the class number (of left ideal classes of $R$) is 4. We choose the following representatives of left ideal classes of $R$:

$$I_1 = R,$$

$$I_2 = At + A\alpha + A\beta + A\alpha\beta,$$

$$I_3 = A(t + 1) + A(t + 1)\alpha + A\beta + A\alpha\beta,$$

$$I_4 = A(t - 1) + A(t - 1)\alpha + A\beta + A\alpha\beta.$$
Note that these ideals are in fact two-sided, and the norm form on each of them can be easily written down. We calculate the following Brandt matrices:

\[
B(t) = \begin{pmatrix}
0 & 1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
\end{pmatrix},
B(t+1) = \begin{pmatrix}
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
\end{pmatrix},
B(t-1) = \begin{pmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
\end{pmatrix}.
\]

Since we have \(T_t f_E = f_E, T_{t+1} f_E = -f_E, T_{t-1} f_E = -f_E\), and the Gross height \(< e_{f_E}, e_{f_E} >= f_E(0) = 1\), the corresponding point \(e_{f_E}\) in \(\text{Pic}(X_{N_0}) \otimes \mathbb{Q}\) can only be \(\pm [1/4, 1/4, -1/4, -1/4]\).

The class number of \(O_K(= A[\sqrt{D}])\) is 1. Choose the Gross point \(x\) in the first component of \(X_{N_0}\) corresponding to the embedding \(K \hookrightarrow D\) which maps \(\sqrt{D}\) to \(\alpha + \beta\). Then \(e_x = [1, 0, 0, 0]\) in \(\text{Pic}(X_{N_0}) \otimes \mathbb{Q}\). Therefore

\[< e_{f_E, 1_D}, e_{f_E, 1_D} >= < e_{f_E}, e_x >^2 = (4 \cdot 1/4)^2 = 1\]

and

\[\frac{(f_E, f_E)}{q^{2(\deg D+1)}} < e_{f_E, 1_D}, e_{f_E, 1_D} > = \frac{32}{9} = L(E/K, 1).\]

Appendix

A  Jacquet-Langlands correspondence and multiplicity one theorem

Let \(\varpi\) be a Hecke character on \(k^\times \backslash A_k^\times\). Let \(D\) be a quaternion algebra over \(k\) and set \(D_{\mathfrak{A}_k} := D \otimes_k \mathfrak{A}_k\). We embed \(A_k\) into \(D_{\mathfrak{A}_k}\) by \(a \mapsto 1 \otimes a\). A \(\mathbb{C}\)-valued function \(f\) on \(D_{\mathfrak{A}_k}^\times\) is called an automorphic form on \(D_{\mathfrak{A}_k}^\times\) (for \(K\)) with central character \(\varpi\) if \(f\) is a function on the double coset space

\[D_{\mathfrak{A}_k}^\times / K\]

for an open compact subgroup \(K\) of \(D_{\mathfrak{A}_k}^\times\) satisfying that for all \(g\) in \(D_{\mathfrak{A}_k}^\times\) and \(a\) in \(A_k^\times\)

\[f(ag) = \varpi(a)f(g)\]

Suppose \(D = \text{Mat}_2(k)\). Then \(D_{\mathfrak{A}_k}^\times = \text{GL}_2(k)\) and \(D_{\mathfrak{A}_k}^\times = \text{GL}_2(A_k)\). \(f\) is called a cusp form if for all \(g\) in \(\text{GL}_2(A_k)\)

\[\int_{k^1 A_k} f \left( \begin{pmatrix} 1 & u \\ 0 & 1 \end{pmatrix} g \right) du = 0.\]
We denote $A_0(\varpi)$ to be the space of automorphic cusp forms on $GL_2(\mathbb{A}_k)$ with central character $\varpi$.

We recall Jacquet-Langlands correspondence in §A.1 and use newform theory to explain the claim in §2.3. In §A.2 we use multiplicity one theorem to show that the space $M_{\text{new}}(\Gamma_0(N_0))$ in §2.3 is a free $T_\mathbb{C}$-module of rank one.

A.1 Jacquet-Langlands correspondence

Let $D = D(N_0)$ be a definite quaternion algebra over $k$ where $N_0$ is the product of finite ramified primes of $D$. Let $\Lambda'(\varpi)$ be the space of automorphic forms on $D \times A_k$ with central character $\varpi$. Jacquet-Langlands correspondence describes the connection between $\Lambda'(\varpi)$ and $A_0(\varpi)$:

([9] Chapter 3, Theorem 14.4 and Theorem 16.1) If an irreducible admissible representation $\rho' = \otimes_v \rho'_v$ is a constituent of $\Lambda'(\varpi)$ and $\rho'_P$ is infinite dimensional for all finite primes $P$ which are prime to $N_0$, then there exist an irreducible admissible representation $\rho(=: \rho'^{\text{JL}})$ which is a constituent of $A_0(\varpi)$ so that

$$L(s, \varpi' \otimes \rho) = L(s, \varpi' \otimes \rho')$$

for all Hecke characters $\varpi'$.

Note that $\rho = \otimes_v \rho_v$ where $\rho_v = \rho'_v$ for finite primes $v$ not dividing $N_0$. Moreover, for the ramified primes $v$ of $D$, $\rho_v$ is determined from $\rho'_v$ via theta correspondence.

Conversely, suppose $\rho = \otimes_v \rho_v$ is a constituent of $A_0(\varpi)$. If for every ramified primes $v$ of $D$ the representation $\rho_v$ is special or supercuspidal, then there is a constituent $\rho' = \otimes_v \rho'_v$ of $\Lambda'(\varpi)$ such that $\rho_v = \rho'_v^{\text{JL}}$. In particular, $\rho'_v$ is one dimensional for ramified prime $v$ if and only if $\rho_v$ is special.

Let $R$ be a fixed maximal order of $D$. From Jacquet-Langlands correspondence one has an isomorphism $\Psi$ between

$$\{ \mathbb{C}-valued \ non-constant \ functions \ on \ \hat{\mathbb{R}}^\times \setminus \hat{D}^\times / D^\times \}$$

and

$$\{ \text{Drinfeld type new forms on } \Gamma_0(N_0) \setminus \text{GL}_2(k_\infty) / \Gamma_\infty k_\infty^\times \}$$

which satisfies

$$\Psi(t_m f) = T_m \Psi(f)$$

for all non-constant functions $f$ on $\hat{\mathbb{R}}^\times \setminus \hat{D}^\times / D^\times$ and monic polynomials $m$ in $A$. We briefly recall the argument in the following and refer the reader to [9] for further details.

Fix $\varpi = \otimes_v \varpi_v$ to be the trivial Hecke character on $k^\times \setminus \mathbb{A}_k^\times$. Let $v$ be a prime of $k$, $\mathcal{O}_v$ be the valuation ring in $k_v$, and $\pi_v$ a uniformizer in $\mathcal{O}_v$. Recall that an
irreducible admissible infinite-dimensional representation \((\rho_v, V_v)\) of \(GL_2(k_v)\) with central character \(\varpi_v\) has conductor \(c^{(v)}\) if \(\pi_v^{(c)}\mathcal{O}_v\) is the largest ideal of \(\mathcal{O}_v\) such that the space of elements \(u \in V_v\) with
\[
\rho_v(g_v)u = u \quad \text{for all} \quad g_v \in GL_2(k_v)
\]
is non-empty. In fact, it is one dimensional. Here
\[
\mathcal{X}_0^{c(v)} = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in GL_2(\mathcal{O}_v) : c \in \pi_v^{(c)}\mathcal{O}_v \right\}.
\]
It is known that
\[
c(v) = \begin{cases} 
0 & \text{if } \rho_v \text{ is an unramified principal series}, \\
1 & \text{if } \rho_v \text{ is an unramified special representation}, \\
\geq 2 & \text{if } \rho_v \text{ is supercuspidal or ramified}.
\end{cases}
\]
Let \((\rho, V) = \bigotimes_v (\rho_v, V_v)\) be a constituent of \(A_0(\varpi)\). The conductor of \(\rho\) is:
\[
\prod_v c^{(v)}.
\]
The space of elements \(f \in V\) with
\[
\rho(g)f = f \quad \text{for all} \quad g \in \prod_v \mathcal{X}_0^{c(v)}
\]
is one dimensional, and called the space of new-forms of \(\rho\). Any new-form \(f\) of \(\rho\) is a Hecke eigenform, i.e. \(T_vf = a_v f\) for all \(v\) where \(a_v \in \mathbb{C}\).

Recall that \(L(s, \rho) = \prod_v L(s, \rho_v)\), where
\[
L(s, \rho_v) = (1 - \chi_{v,1}(\pi_v)q^{-s \deg v})^{-1} \cdot (1 - \chi_{v,2}(\pi_v)q^{-s \deg v})^{-1}
\]
if \(\rho_v\) is an unramified principal series \(\pi(\chi_{v,1}, \chi_{v,2})\);
\[
L(s, \rho_v) = (1 - \chi_v(\pi_v)q^{-(s+1/2) \deg v})^{-1}
\]
if \(\rho_v\) is an unramified special representation \(\text{sp}(\chi_v \cdot |v|^{1/2}, \chi_v \cdot |v|^{-1/2})\);
\[
L(s, \rho_v) = 1
\]
if \(\rho_v\) is supercuspidal or ramified. Here \(\chi_{v,1}, \chi_{v,2},\) and \(\chi_v\) are unramified characters of \(k_v^\times\) with \(\chi_{v,1} \cdot \chi_{v,2} = 1 = \chi_v^2\). It is known that
\[
a_v = \begin{cases} 
q^{\frac{1}{2} \deg v}(\chi_{v,1}(\pi_v) + \chi_{v,2}(\pi_v)) & \text{if } \rho_v \cong \pi(\chi_{v,1}, \chi_{v,2}), \\
\chi_v(\pi_v) & \text{if } \rho_v \cong \text{sp}(\chi_v \cdot |v|^{1/2}, \chi_v \cdot |v|^{-1/2}).
\end{cases}
\]
Suppose $\rho = \otimes_v \rho_v$ is of conductor $N_0\infty$ and $\rho_\infty \cong \text{sp}(|\cdot|^{1/2}, |\cdot|^{-1/2})$. Then new-forms of $\rho$ are functions on

$$GL_2(k) \backslash GL_2(A_k)/K_0(N_0\infty)k_\infty^\times.$$ 

From the bijection in §2.1

$$GL_2(k) \backslash GL_2(A_k)/K_0(N_0\infty)k_\infty^\times \cong \Gamma_0(N_0) \backslash GL_2(k_\infty)/\Gamma_\infty k_\infty^\times,$$

new-forms of such $\rho$ can be viewed as newforms of Drinfeld type for $\Gamma_0(N_0)$. In fact, the space $S^{\text{new}}(\Gamma_0(N_0))$ of Drinfeld type new forms for $\Gamma_0(N_0)$ is spanned by the new-forms of such $\rho$ with conductor $N_0\infty$.

Since $\rho$ is of conductor $N_0\infty$, $\rho_P \cong \text{sp}(\chi_P| \cdot|^{1/2}, \chi_P| \cdot|^{-1/2})$ for all $P | N_0$ where $\chi_P$ is an unramified character of $k_P^\times$ with $\chi_P^2 = 1$. By Jacquet-Langlands correspondence we can find an irreducible constituent $(\rho', V') = \otimes_v \rho'_v$ of $A'(\infty)$ so that $\rho = \rho'^{\text{Dr}}$. In this case, $\rho'_P = \chi_P \circ \text{Nr}$ for $P | N_0$ and $\rho'_\infty$ is the trivial representation. Therefore we can find a subspace of elements $f' \in V'$ which are non-constant functions on

$$\mathcal{D}^\times \backslash \hat{\mathcal{D}}^\times / \hat{\mathcal{R}}^\times.$$

This subspace is also one dimensional, called the space of new-forms of $\rho'$. Any new-form $f'$ of $\rho'$ is also a Hecke eigenform, i.e. $t_v f' = a'_v f'$, where $a'_v$ appears in the local factor $L_v(s, \rho'_v)$. Since for any place $v$

$$L(s, \rho_v) = L(s, \rho'_v),$$

we have $a_v = a'_v$.

In fact, the space of non-constant functions on $\mathcal{D}^\times \backslash \hat{\mathcal{D}}^\times / \hat{\mathcal{R}}^\times$ is generated by new-forms such that $\rho' = \otimes_v \rho'_v$ where $\rho'_\infty$ is trivial and for $P | N_0$, $\rho'_P = \chi_P \circ \text{Nr}$ for an unramified character $\chi_P$ of $k_P^\times$ with $\chi_P^2 = 1$. By taking conjugate, we identify functions on $\mathcal{D}^\times \backslash \hat{\mathcal{D}}^\times / \hat{\mathcal{D}}^\times$ with functions on $\hat{\mathcal{R}}^\times \backslash \hat{\mathcal{D}}^\times / \mathcal{D}^\times$. From the dimension formula at the end of §2.2 we have a bijective map $\Psi$ from

$$\{ \text{C-valued non-constant functions on } \hat{\mathcal{R}}^\times \backslash \hat{\mathcal{D}}^\times / \mathcal{D}^\times \}$$

to

$$\{ \text{Drinfeld type new forms on } \Gamma_0(N_0) \backslash GL_2(k_\infty)/\Gamma_\infty k_\infty^\times \}$$

so that for each monic polynomial $m$ in $A$,

$$\Psi(t_m f) = T_m \Psi(f).$$

Since constant functions on $\hat{\mathcal{R}}^\times \backslash \hat{\mathcal{D}}^\times / \mathcal{D}^\times$ are eigenfunctions of $t_m$ with eigenvalue $\sigma(m)_{N_0}$, we extend $\Psi$ by mapping constant functions into the one
Consider the definite Shimura curve $X = X_{N_0}$. We have a canonical bijection between components of $X$ and ideal classes of $R$ and this gives the canonical isomorphism

$$\{ \text{(C-valued) functions on } \hat{R}^x \backslash \hat{D}^x / \hat{D}^x \} \cong \text{Hom}(\text{Pic}(X), \mathbb{C}) \cong \text{Pic}(X)^\vee \otimes \mathbb{C}. $$

Therefore one has:

**Theorem A.1.** $\Psi : \text{Pic}(X)^\vee \otimes \mathbb{C} \cong M_{\text{new}}(\Gamma_0(N_0))$ is an isomorphism so that $\Psi(t_m f) = T_m \Psi(f)$ for any monic polynomial $m$ in $A$. Moreover,

$$\text{Tr}(t_m) = \text{Tr}(T_m)$$

and so the $\mathbb{C}$-algebra $T_C$ generated by Hecke correspondences $t_m$ on $X$ is isomorphic to the $\mathbb{C}$-algebra generated by Hecke operators $T_m$ on $M_{\text{new}}(\Gamma_0(N_0))$.

**A.2 Multiplicity one theorem**

Let $\varpi : \mathbb{A}_k^x / \mathbb{A}_k^x$ be a Hecke character. Let $\rho_1 = \otimes_v \rho_{1,v}$ and $\rho_2 = \otimes_v \rho_{2,v}$ be two irreducible admissible representations which are constituents of $A_0(\varpi)$. The *multiplicity one theorem* (cf. [3]) tells us that $\rho_1 = \rho_2$ if and only if

$$\rho_{1,v} \cong \rho_{2,v}$$

for all place $v$.

Fix $\varpi$ to be trivial. Choose two irreducible admissible representations $\rho_1 = \otimes_v \rho_{1,v}$ and $\rho_2 = \otimes_v \rho_{2,v}$ of conductor $N_0 \infty$ which are constituents of $A_0(\varpi)$ satisfying

$$\rho_{1,\infty} \cong \rho_{2,\infty} \cong \text{sp}(\{ | \cdot |_{\infty}^{1/2}, | \cdot |_{\infty}^{-1/2} \})$$

and $\rho_{1,P}$ and $\rho_{2,P}$ are unramified special representations for $P | N_0$. Let $f_1$ and $f_2$ be new-forms of $\rho_1$ and $\rho_2$ respectively. Then $T_P f_i = a_{P,i} f_i$ where $a_{P,i} \in \mathbb{C}$ for $i = 1, 2$ and all prime $P$ in $A$. If $a_{P,1} = a_{P,2}$ for all $P$, then $L_P(s, \rho_{1,P}) = L_P(s, \rho_{2,P})$ and so

$$\rho_{1,P} \cong \rho_{2,P}$$

for all $P$. By multiplicity one theorem we have $\rho_1 = \rho_2$ and so $f_1, f_2$ are linearly dependent.

Recall that $M_{\text{new}}(\Gamma_0(N_0)) = S_{\text{new}}(\Gamma_0(N_0)) \oplus \mathbb{C}E_{N_0}$ for $\Gamma_0(P_0)$. As a $T_C$-module, the space $M_{\text{new}}(\Gamma_0(N_0))$ is a direct sum $(\oplus_i \mathbb{C}f_i) \oplus \mathbb{C}E_{N_0}$ of one dimensional submodules and each $f_i$ is a new-form of an irreducible admissible representation $\rho_i = \otimes_v \rho_{i,v}$ which is a constituent of $A_0(\varpi)$ with

$$\rho_{i,\infty} \cong \text{sp}(\{ | \cdot |_{\infty}^{1/2}, | \cdot |_{\infty}^{-1/2} \})$$
and $\rho_{i,P}$ is an unramified special representation for $P \mid N_0$. According to multiplicity one theorem, each pair of these one dimensional submodules are non-isomorphic. Therefore $M_{\text{new}}(\Gamma_0(N_0))$ is a cyclic $\mathbb{T}_C$-module, which is generated by $E_{N_0} + \sum_i f_i$. Viewing $\mathbb{T}_C$ as a subring of $\text{End}_C(M_{\text{new}}(\Gamma_0(N_0)))$, we have

$$\dim_\mathbb{C} \mathbb{T}_C \leq \dim_\mathbb{C} M_{\text{new}}(\Gamma_0(N_0)).$$

Therefore

**Proposition A.2.** The space $M_{\text{new}}(\Gamma_0(N_0))$ is a free $\mathbb{T}_C$-module of rank one.

**B Transformation law of theta series**

Fix a definite quaternion algebra $D = D(N_0)$ where $N_0$ is the product of finite ramified primes of $D$. Let $R$ be a maximal order and $n$ be the class number. In this section we deduce the transformation law of the theta series $\theta_{ij}$ for $1 \leq i, j \leq n$ introduced in §2.1.1. Recall that for each $(i, j)$, theta series $\theta_{ij}$ is a function on $\mathbb{k} \times \mathbb{\infty} \times \mathbb{k} \mathbb{\infty}$:

$$\theta_{ij}(x, y) = \sum_{b \in M_{ij}} \phi_\infty(\frac{\text{Nr}(b) x^2 t^2}{N_{ij}}) \cdot \psi_\infty(\frac{\text{Nr}(b) y}{N_{ij}}),$$

where $\phi_\infty$ is the characteristic function of $0_\infty$ and $\psi_\infty$ is the fixed additive character on $k_\infty$.

**B.1 Fourier Transform**

Let $D_\infty = D \otimes_k k_\infty$. For $\alpha, \beta \in k_\infty^\times$ with $v_\infty(\alpha) > v_\infty(\beta) - 2$, let

$$\Phi_{\alpha, \beta} : D_\infty \rightarrow \mathbb{C}$$

$$w \mapsto \phi_\infty(\text{Nr}(w)\alpha)\psi_\infty(\text{Nr}(w)\beta).$$

Define $[\cdot, \cdot] : D_\infty \times D_\infty \rightarrow \mathbb{C}^\times$ by $[w, w^*] := \psi_\infty(\text{Tr}(ww^*)).$ The Fourier transform of $\Phi_{\alpha, \beta}$ is given by:

$$\Phi_{\alpha, \beta}^*(w^*) := \int_{D_\infty} \Phi_{\alpha, \beta}(w)[w, w^*]dw,$$

for all $w^*$ in $k_\infty$.

where $dw$ is a Haar measure on $D_\infty$.

We define

$$S(\alpha, \beta, dw) := \int_{D_\infty} \phi_\infty(\text{Nr}(w)\alpha)\psi_\infty(\text{Nr}(w)\beta)dw.$$

Then $\Phi_{\alpha, \beta}^*(w^*)$ is equal to

$$S(\alpha, \beta, dw)\phi_\infty(\frac{\text{Nr}(w^*)^\alpha}{\beta^2})\psi_\infty(\frac{\text{Nr}(w^*)^{-1}}{\beta}).$$
More generally, take $h \in k_{\infty}^{\times}$, $\rho \in D_{\infty}$. For $\alpha, \beta \in k_{\infty}^{\times}$ with $v_{\infty}(\alpha) > v_{\infty}(\beta) - 2$, let $\Psi_{\alpha, \beta}(w) := \Phi_{\alpha, \beta}(\rho + hw)$. Then $\Psi_{\alpha, \beta}(w^*)$ is equal to

$$q^{4v_{\infty}(h)} S(\alpha, \beta, dw) \phi_{\infty}(\operatorname{Nr}(\frac{w^*}{h})^\alpha \beta^2) \psi_{\infty}(\operatorname{Nr}(\frac{w^*}{h})^\alpha \beta^2) \psi_{\infty}(\operatorname{Tr}(\frac{\rho w^*}{h})).$$

**B.2 Poisson summation**

Let $O_{D_{\infty}}$ be the maximal order of $D_{\infty}$. For $v_{\infty}(\alpha) > v_{\infty}(\beta) - 2$, we have

$$S(\alpha, \beta, dw) = q^{2v_{\infty}(\beta) - 3} \cdot dw(O_{D_{\infty}}).$$

For the pair $(i, j)$, $1 \leq i, j \leq n$, we choose Haar measure $dw$ with $dw(D_{\infty}/M_{ij}) = 1$ and denote the integral $S(\alpha, \beta, dw)$ by $S(\alpha, \beta, M_{ij})$. Then

$$S(\alpha, \beta, M_{ij}) = q^{2v_{\infty}(\beta) - \deg(N_\alpha)} \cdot q^{2v_{\infty}(N_{ij})}.$$

Let $\tilde{M}_{ij}$ be the dual lattice of $M_{ij}$, i.e.,

$$\tilde{M}_{ij} = \{ w \in D_{\infty} : \operatorname{Tr}(w\mu) \in A \text{ for all } \mu \in M_{ij} \}.$$

We apply the Poisson summation formula

$$\sum_{\mu \in M_{ij}} \Psi_{\alpha, \beta}(\mu) = \sum_{\mu^* \in \tilde{M}_{ij}} \Psi_{\alpha, \beta}(\mu^*)$$

and get

**Proposition B.1.** Let $\alpha, \beta \in k_{\infty}^{\times}$ with $v_{\infty}(\alpha) > v_{\infty}(\beta) - 2$, $h \in k_{\infty}^{\times}$, $\rho \in D_{\infty}$. Then

$$\sum_{\mu \in M_{ij}} \phi_{\infty}(\operatorname{Nr}(\rho + h\mu)\alpha) \psi_{\infty}(\operatorname{Nr}(\rho + h\mu)\beta)$$

$$= q^{4v_{\infty}(h)} S(\alpha, \beta, M_{ij}) \sum_{\mu^* \in \tilde{M}_{ij}} \phi_{\infty}(\operatorname{Nr}(\frac{\mu^*}{h})^\alpha \beta^2) \psi_{\infty}(\operatorname{Nr}(\frac{\mu^*}{h})^\alpha \beta^2) \psi_{\infty}(\operatorname{Tr}(\frac{\rho \mu^*}{h})).$$

Let $x \in k_{\infty}^{\times}$, $y \in k_{\infty}^{\times}$, $M \subset D_{\infty}$ a discrete $A$-lattice, $N_M \in k$ such that $N_M \cdot A$ is the fractional ideal of $A$ generated by $\operatorname{Nr}(\mu)$ for $\mu \in M$. For $h \in A$ with $h \neq 0$, $\rho \in M$, define “partial theta” series:

$$\theta(x, y, M, N_M, h, \rho) := \sum_{\mu \in M, \mu \equiv \rho \mod hM} \phi_{\infty}(\frac{\operatorname{Nr}(\mu) x f^2}{N_M h}) \psi_{\infty}(\frac{\operatorname{Nr}(\mu) y}{N_M h}).$$

Note that $\theta_{ij}(x, y) = \theta(x, y, M_{ij}, N_{ij}, 1, 0)$, and

$$\theta(x, y, M, N_M, h, \rho) = \sum_{\mu \in M} \phi_{\infty}(\operatorname{Nr}(\rho + h\mu)\alpha) \psi_{\infty}(\operatorname{Nr}(\rho + h\mu)\beta)$$

where $\alpha = \frac{x f^2}{N_M h}$, $\beta = \frac{y}{N_M h}$. 
Proposition B.2. Let \( x, y \in k_\infty^x, \nu_\infty(x) > \nu_\infty(y), 0 \neq h \in A, \kappa \in \hat{M}_{ij}. \) Then

\[
\frac{x}{y^2}, -\frac{1}{y} M_{ij}, N_{ij}^{-1} N_0^{-1}, h, \kappa
\]

\[
= S \left( \frac{xt^2}{N_{ij}N_0 h}, \frac{y}{N_{ij}N_0 h}, M_{ij} \right)^{-1} \sum_{\rho \in M_{ij}/h\hat{M}_{ij}} \psi_\infty(\text{Tr}(\frac{\rho k}{h})) \theta \left( \frac{x}{N_0}, \frac{y}{N_0}, M_{ij}, N_{ij}, h, \rho \right). 
\]

Proof. By Proposition B.1 we have

\[
\theta(x, y, M_{ij}, N_{ij}, h, \rho) = q^{4\nu_\infty(h)} S(\alpha, \beta, M_{ij}) \sum_{\mu^* \in \hat{M}_{ij}} \phi_\infty \left( \text{Nr} \left( \frac{\mu^*}{h} \frac{\alpha}{\beta^2} \right) \psi_\infty \left( \text{Nr} \left( \frac{\mu^*}{h} \frac{1}{\beta} \right) \psi_\infty \left( \text{Tr} \left( \frac{-\rho \mu^*}{h} \right) \right) \right).
\]

Multiply this by \( \psi_\infty \left( \text{Tr} \left( \frac{\alpha \beta}{h} \right) \right) \) for \( \kappa \in \hat{M}_{ij} \) and sum over \( \rho \in M_{ij}/h\hat{M}_{ij}, \) we obtain

\[
\sum_{\rho \in M_{ij}/h\hat{M}_{ij}} \psi_\infty \left( \text{Tr} \left( \frac{\rho k}{h} \right) \right) \cdot \theta(x, y, M_{ij}, N_{ij}, h, \rho) = q^{4\nu_\infty(h)} S(\alpha, \beta, M_{ij}) \sum_{\mu^* \in \hat{M}_{ij}} \left\{ \phi_\infty \left( \text{Nr} \left( \frac{\mu^*}{h} \frac{\alpha}{\beta^2} \right) \psi_\infty \left( \text{Nr} \left( \frac{\mu^*}{h} \frac{1}{\beta} \right) \psi_\infty \left( \text{Tr} \left( \frac{-\rho \mu^*}{h} \right) \right) \right) \right\}.
\]

Since

\[
\sum_{\rho \in M_{ij}/h\hat{M}_{ij}} \psi_\infty \left( \text{Tr} \left( \frac{\rho k}{h} (\kappa - \mu^*) \right) \right) = \begin{cases} 
0 & \text{if } \mu^* - \kappa \notin h\hat{M}_{ij}, \\
q^{-4\nu_\infty(h)} & \text{if } \mu^* - \kappa \in h\hat{M}_{ij}.
\end{cases}
\]

The proposition follows by replacing \( x \) with \( \frac{x}{N_0} \), and \( y \) with \( \frac{y}{N_0} \).

B.3 Transformation law

Let \( (x, y) \in k_\infty^x \times k_\infty^y \). Suppose a matrix \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{GL}_2(A) \) is given such that \( cy + d \neq 0 \). We define

\[
\gamma \circ (x, y) := \begin{pmatrix} x(ad - bc) & ay + b \\ (cy + d)^2 & cy + d \end{pmatrix}.
\]

Lemma B.3. Suppose \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(A), c \equiv 0 \mod N_0, \nu_\infty(x) > \nu_\infty(y), \)
and $v_\infty(cx) > v_\infty(cy + d)$. Let $1 \leq i, j \leq n$. Then

$$
\theta_{ij}(\gamma \circ (x, y)) = S(N_{ij}xt^2 \quad \eta - N_{ij}(cy + d) \quad M_{ij})^{-1} \cdot S(xt^2 \quad y \quad M_{ij})^{-1}
\cdot \left( \sum_{\kappa \in M_{ij}/dM_{ij}} \psi_\infty \left( \frac{\text{nr}(b)}{N_{ij}d} \right) \theta_{ij}(x, y) \right).
$$

Proof. Put $u = \frac{x}{y^2}$, $v = \frac{-1}{y}$. Then

$$
\theta_{ij}(\gamma \circ (x, y)) = \theta \left( \frac{u}{(c - du)^2}, \frac{b}{d(c - du)}, M_{ij}, N_{ij}, 1, 0 \right)
= \sum_{\kappa \in M_{ij}/dM_{ij}} \theta \left( \frac{du}{c - dv}, \frac{-1}{c - dv}, M_{ij}, N_{ij}, d, \kappa \right)
= \sum_{\kappa \in M_{ij}/dM_{ij}} \psi_\infty \left( \frac{\text{nr}(k)b}{N_{ij}d} \right) \theta \left( \frac{du}{d(c - d)}, \frac{-1}{d(c - d)}, M_{ij}, N_{ij}, d, \kappa \right).
$$

Since $v_\infty(cx) > v_\infty(cy + d)$, we have $v_\infty(du) > v_\infty(dv - c)$ and

$$
\theta_{ij}(\gamma \circ (x, y)) = S(N_{ij}ut^2, N_{ij}(v - c/d), M_{ij})^{-1} \cdot \sum_{\kappa \in M_{ij}/dM_{ij}} \left[ \psi_\infty \left( \frac{\text{nr}(k)b}{N_{ij}d} \right) \right].
$$

Since $-c/N_0 \in A$, we have

$$
\theta_{ij}(\gamma \circ (x, y)) = S(N_{ij}ut^2, N_{ij}(v - c/d), M_{ij})^{-1}
\cdot \sum_{\rho \in M_{ij}/dM_{ij}} \left[ \theta \left( \frac{du}{N_0}, \frac{dv}{N_0}, M_{ij}, N_{ij}^{-1}N_0^{-1}, d, \rho \right) \right].
$$

Note that $cN_{ij}\bar{\rho} \in M_{ij}$. Replacing $k$ by $k + cN_{ij}\bar{\rho}$ the last summand equals to

$$
\psi_\infty \left( \frac{\text{nr}(b)}{N_{ij}d} + \text{tr}(\rho \bar{\kappa}) \cdot N_{ij}ac \text{nr}(\rho) \right).
$$

Since $a \text{tr}(\rho \bar{\kappa}) + N_{ij}ac \text{nr}(\rho) \in A$, we have

$$
\theta_{ij}(\gamma \circ (x, y)) = S(N_{ij}ut^2, N_{ij}(v - c/d), M_{ij})^{-1} \cdot \sum_{\kappa \in M_{ij}/dM_{ij}} \psi_\infty \left( \frac{\text{nr}(k)b}{N_{ij}d} \right)
\cdot \theta \left( \frac{u}{N_0}, \frac{v}{N_0}, M_{ij}, N_{ij}^{-1}N_0^{-1}, 1, 0 \right).
$$
Recall that $u = \frac{x}{y^2}$, $v = \frac{1}{y}$. By Proposition B.2 we have

$$
\theta_{ij}(g \circ (x,y)) = S\left(\frac{N_{ij}xt^2}{y^2}, \frac{-N_{ij}(cy+d)}{dy}, \tilde{M}_{ij}\right)^{-1} \cdot S\left(\frac{xt^2}{N_{ij}}, \frac{y}{N_{ij}}, M_{ij}\right)^{-1} \cdot \sum_{\kappa \in M_{ij}/dM_{ij}} \psi_{\infty}\left(\frac{N_{ij}(\kappa)b}{N_{ij}d}\right) \theta_{ij}(x,y).
$$

Note that

$$
S\left(\frac{N_{ij}xt^2}{y^2}, \frac{-N_{ij}(cy+d)}{dy}, \tilde{M}_{ij}\right) \cdot S\left(\frac{xt^2}{N_{ij}}, \frac{y}{N_{ij}}, M_{ij}\right) = q^{2v_{\infty}(cy+d)+2\deg d}.
$$

By standard argument we get

$$
\sum_{\kappa \in M_{ij}/dM_{ij}} \psi_{\infty}\left(\frac{N_{ij}(\kappa)b}{N_{ij}d}\right) = q^{2\deg(d)}.
$$

Since $\theta_{ij}(x,y) = \theta_{ij}(x,y+h)$ for any $h \in A$, we can drop the assumption $v_{\infty}(x) > v_{\infty}(y)$ and obtain the transformation law of $\theta_{ij}$:

**Theorem B.4.** For $1 \leq i,j \leq n$. Let $x \in k_\infty^\times$, $y \in k_\infty$, $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(A)$. Assume $v_{\infty}(cx) > v_{\infty}(cy+d)$, and $c \equiv 0 \mod N_0$. Then

$$
\theta_{ij}(\gamma \circ (x,y)) = q^{-2v_{\infty}(cy+d)} \cdot \theta_{ij}(x,y).
$$
