TWO-WEIGHT INEQUALITY FOR THE HILBERT TRANSFORM: A REAL VARIABLE CHARACTERIZATION, I

MICHAEL T. LACEY, ERIC T. SAWYER, CHUN-YEN SHEN, and IGNACIO URIARTE-TUERO

Abstract
Let $\sigma$ and $w$ be locally finite positive Borel measures on $\mathbb{R}$ which do not share a common point mass. Assume that the pair of weights satisfy a Poisson $A_2$ condition, and satisfy the testing conditions below, for the Hilbert transform $H$,

$$\int_I H(\sigma 1_I)^2 \, dw \lesssim \sigma(I), \quad \int_I H(w 1_I)^2 \, d\sigma \lesssim w(I),$$

with constants independent of the choice of interval $I$. Then $H(\cdot)$ maps $L^2(\sigma)$ to $L^2(w)$, verifying a conjecture of Nazarov, Treil, and Volberg. The proof has two components, a global-to-local reduction, carried out in this article, and an analysis of the local problem, to be elaborated in a future Part II version of this article.

1. Introduction
Define a truncated Hilbert transform of a locally bounded signed measure $\nu$ by

$$H_{\epsilon, \delta}\nu(x) := \int_{\epsilon < |y-x| < \delta} \frac{d\nu(y)}{y-x}, \quad 0 < \epsilon < \delta.$$ 

Given weights (i.e., locally bounded positive Borel measures) $\sigma$ and $w$ on the real line $\mathbb{R}$, we consider the following two-weight norm inequality for the Hilbert transform,

$$\sup_{0 < \epsilon < \delta} \int_{\mathbb{R}} |H_{\epsilon, \delta}(f \sigma)|^2 \, dw \leq N^2 \int_{\mathbb{R}} |f|^2 \, d\sigma, \quad f \in L^2(\sigma), \quad (1.1)$$

where $\mathcal{N}$ is the best constant in the inequality, uniform over all truncations of the Hilbert transform kernel. Below, will write the inequality above as $\| H(f\sigma) \|_{L^2(w)} \leq \mathcal{N} \| f \|_{L^2(\hat{w})}$, that is, the uniformity over the truncation parameters is suppressed.

The primary question is to find a real variable characterization of this inequality, and the theorem below is an answer to the beautiful conjecture of Nazarov, Treil, and Volberg (see [29, p. 127]). Set

$$P(\sigma, I) := \int_{\mathbb{R}} \frac{|I|}{|I|^2 + \text{dist}(x, I)^2} \sigma(dx),$$

which is approximately the Poisson extension of $\sigma$ to the upper half-plane, evaluated at $(x_I, |I|)$, where $x_I$ is the center of $I$.

**THEOREM 1.2**

Let $\sigma$ and $w$ be locally finite positive Borel measures on the real line $\mathbb{R}$ with no common point masses. Then, the two-weight inequality (1.1) holds if and only if these three conditions hold uniformly over all intervals $I$:

$$P(\sigma, I)P(w, I) \leq \mathcal{A}_2,$$  

(1.3)

$$\int_I |H(1_I\sigma)|^2 \, dw \leq \mathcal{T}^2 \sigma(I), \quad \int_I |H(1_Iw)|^2 \, d\sigma \leq \mathcal{T}^2 w(I).$$  

(1.4)

We have

$$\mathcal{N} \approx \mathcal{A}_2^{1/2} + \mathcal{T} =: \mathcal{H},$$  

(1.5)

where $\mathcal{A}_2$ and $\mathcal{T}$ are the best constants in the inequalities above.

It is well known (see [29]) that the $A_2$ condition is necessary for the norm inequality, and the inequalities (1.4) are obviously necessary, thus the content of the theorem is the sufficiency of the $A_2$ and testing inequalities. In the present article we will carry out a global-to-local reduction in the proof of sufficiency, while the analysis of the local problem will be made in a future article (Part II of this series; see [5]).

The Nazarov–Treil–Volberg conjecture has only been verified before under additional hypotheses on the pair of weights, hypotheses which are not necessary for the two-weight inequality. The so-called pivotal condition of [29] is not necessary, as was proved in [9]. The pivotal condition is still an interesting condition: It is all that is needed to characterize the boundedness of the Hilbert transform, together with the maximal function in both directions. But, the boundedness of this triple of operators is decoupled in the two-weight setting (see [24]).
Our argument has these attributes. Certain degeneracies of the pair of weights must be addressed, such as the contribution made by Nazarov, Treil, and Volberg in their innovative 2004 paper [18] (see also [29]), which was further sharpened with the property of energy in [9], a crucial property of the Hilbert transform. This theme is further developed in the following pages, with the notion of functional energy explained in Section 5.

The proof should proceed through the analysis of the bilinear form $\langle H(\sigma f), gw \rangle$, as one expects certain paraproducts to appear. Still, the paraproducts have no canonical form, suggesting that the proof is highly nonlinear in $f$ and $g$. The nonlinear point of view was initiated in [7] and is central to our work here. A particular feature of our arguments is a repeated appeal to certain quasiorthogonality arguments, providing (many) simplifications over prior arguments. For instance, we never find ourselves constructing auxiliary measures, and verifying that they are Carleson, a frequent step in many related arguments.

One can phrase a two-weight inequality question for any operator $T$, a question that became apparent with the foundational paper of Muckenhoupt [12] on $A_p$ weights for the maximal function. Indeed, the case of Hardy’s inequality was quickly resolved by Muckenhoupt [11]. The maximal function was resolved by the second author in [26], as well as the fractional integrals, and, essential for this paper, Poisson integrals (see [27]). The latter paper established a result which closely paralleled the contemporaneous $T1$ theorem of David and Journé [1]. This connection, fundamental in nature, was not fully appreciated until the innovative work of Nazarov, Treil, and Volberg [14]–[16] in developing a nonhomogeneous theory of singular integrals. The two-weight problem for dyadic singular integrals was only resolved recently in [17]. Partial information about the two-weight problem for singular integrals in [21] was basic to the resolution of the $A_2$ conjecture in [3], and several related results (see [4], [6], [21], [22]). Our result is the first real variable characterization of a two-weight inequality for a continuous singular integral.

Interest in the two-weight problem for the Hilbert transform arises from its natural occurrence in questions related to operator theory (see [20], [25]), spectral theory (see [20]), model spaces (see [23]), and analytic function spaces (see [10]). In the context of operator theory, Sarason posed the conjecture (see [2]) that the Hilbert transform would be bounded if the pair of weights satisfied the (full) Poisson $A_2$ condition. This was disproved by Nazarov [13]. Advances on these questions have been linked to a finer understanding of the two-weight question (see, e.g., [19], [20]) built upon Nazarov’s counterexample.
2. Dyadic grids and Haar functions

2.1. Choice of truncation

We have stated the main theorem with hard cutoffs in the truncation of the Hilbert transform. There are many possible variants in the choice of truncation; moreover, the proof of sufficiency requires a different choice of truncation.

Consider a truncation given by

\[ \tilde{H}_{\alpha, \beta}(\sigma f)(x) := \int f(y) K_{\alpha, \beta}(y - x) \sigma(dy), \]

where \( K_{\alpha, \beta}(y) \) is chosen to minimize the technicalities associated with off-diagonal considerations. Specifically, set \( K_{\alpha, \beta}(0) = 0 \), and otherwise \( K_{\alpha, \beta}(y) \) is odd and for \( y > 0 \),

\[
K_{\alpha, \beta}(y) := \begin{cases} 
-\frac{y}{\alpha^2} + \frac{2}{\alpha} & 0 < y < \alpha, \\
\frac{1}{y} & \alpha \leq y \leq \beta, \\
-\frac{y}{\beta^2} + \frac{2}{\beta} & \beta < y < 2\beta, \\
0 & 2\beta \leq y.
\end{cases}
\]

This is a \( C^1 \) function on \((0, 2\beta)\), and is Lipschitz, convex, and monotone on \((0, \infty)\).

We now argue that we can use these truncations in the proof of the sufficiency bound of our main theorem.

PROPOSITION 2.1

If the pair of weights \( \sigma, w \) satisfy the \( A_2 \) bound (1.3), then one has the uniform norm estimate with the hard truncations (1.1) if and only if one has uniform norm estimate for the smooth truncations,

\[
\sup_{0 < \alpha < \beta} \| \tilde{H}_{\alpha, \beta}(\sigma f) \|_w \leq N \| f \|_\sigma.
\]

Indeed, \( |H_{\alpha, \beta}(\sigma f) - \tilde{H}_{\alpha, \beta}(\sigma f)| \lesssim A_{\alpha}(\sigma |f|) + A_{\beta}(\sigma |f|) \), where these last two operators are single-scale averages, namely,

\[
A_{\alpha}(\sigma \phi)(x) = \alpha^{-1} \int_{(x-3\alpha, x+3\alpha)} \phi(y) \sigma(dy).
\]

But, the (simple) \( A_2 \) bound is all that is needed to provide a uniform bound on the operators \( A_{\alpha}(\sigma \phi) \). So the proposition follows.

Henceforth we use the truncations \( \tilde{H}_{\alpha, \beta} \), and we suppress the tilde in the notation. The particular choice of truncation is motivated by this off-diagonal estimate on the kernels.
Proposition 2.2

Suppose that $2|x - x'| < |x - y|$; then

$$K_{\alpha, \beta}(y - x') - K_{\alpha, \beta}(y - x) = C_{x, x', y} \frac{x' - x}{(y - x)(y - x')}$$

where $C_{x, x', y} = 1$, $2\alpha < |x - y| < \frac{1}{2} \beta$, (2.3)

and is otherwise positive and never more than 4.

Proof

The assumptions imply that $y - x'$ and $y - x$ have the same sign. Assume without loss of generality that $0 < y - x' < y - x$. If $2\alpha < |x - y| < \beta/2$, it follows that $\alpha < |x' - y| < \beta$, and so by the definition,

$$K_{\alpha, \beta}(y - x') - K_{\alpha, \beta}(y - x) = \frac{1}{y - x'} - \frac{1}{y - x} = \frac{x' - x}{(y - x)(y - x')}.$$ 

And, in the general case, we have $|\frac{d}{dt}K_{\alpha, \beta}(t)| \leq 4t^{-2}$, so that

$$0 \leq K_{\alpha, \beta}(y - x') - K_{\alpha, \beta}(y - x) \leq \int_{y-x'}^{y-x} 4 \frac{dt}{t^2} = 4 \frac{x' - x}{(y - x)(y - x')}.$$ 

2.2. Dyadic grids

A collection of intervals $G$ is a grid if for all $G, G' \in G$, we have $G \cap G' \in \{\emptyset, G, G'\}$. By a dyadic grid we mean a grid $\mathcal{D}$ of intervals of $\mathbb{R}$ such that for each interval $I \in \mathcal{D}$, the subcollection $\{I' \in \mathcal{D} : |I'| = |I|\} \subset \mathbb{R}$, aside from endpoints of the intervals. In addition, the left and right halves of $I$, denoted by $I_{\pm}$, are also in $\mathcal{D}$.

For $I \in \mathcal{D}$, the left and right halves $I_{\pm}$ are referred to as the children of $I$. We denote by $\pi_\mathcal{D} I$ the unique interval in $\mathcal{D}$ having $I$ as a child, and we refer to $\pi_\mathcal{D} I$ as the $\mathcal{D}$-parent of $I$.

We will work with subsets $\mathcal{F} \subset \mathcal{D}$. We say that $I$ has $\mathcal{F}$-parent $\pi_\mathcal{F} I = F$ if $F \in \mathcal{F}$ is the minimal element of $\mathcal{F}$ that contains $I$.

2.3. Haar functions

Let $\sigma$ be a weight on $\mathbb{R}$, one that does not assign positive mass to any endpoint of a dyadic grid $\mathcal{D}$. If $I \in \mathcal{D}$ is such that $\sigma$ assigns nonzero weight to both children of $I$, the associated Haar function is

$$h^\sigma_I := \sqrt{\frac{\sigma(I_+)(I_+)}{\sigma(I)}} \left( - \frac{I_-}{\sigma(I_-)} + \frac{I_+}{\sigma(I_+)} \right).$$
In this definition, we are identifying an interval with its indicator function, and we will do so throughout the remainder of the paper. This is an $L^2(\sigma)$-normalized function, and has $\sigma$-integral zero. For any dyadic interval $I_0$, we have that $\{\sigma(I_0)^{-1/2}I_0\} \cup \{h^q_I : I \in \mathcal{D}, I \subset I_0\}$ is an orthogonal basis for $L^2(I_0, \sigma)$.

We will use the notation $\hat{f}(I) = (f, h^q_I)_\sigma$, as well as

$$\Delta^q_I f = (f, h^q_I)_\sigma h^q_I = I_+ \mathbb{E}^q_{I+} f + I_- \mathbb{E}^q_{I-} f - I \mathbb{E}^q_I f.$$ 

The second equality is the familiar martingale difference equality, and so we will refer to $\Delta^q_I f$ as a martingale difference. It implies the familiar telescoping identity $\mathbb{E}^q_I f = \sum_{I: I \supseteq J} \mathbb{E}^q_J \Delta^q_I f$.

For any function the Haar support of $f$ is the collection $\{I \in \mathcal{D} : \hat{f}(I) \neq 0\}$.

### 2.4. Good-bad decomposition

With a choice of dyadic grid $\mathcal{D}$ understood, we say that $J \in \mathcal{D}$ is $(\epsilon, r)$-good if and only if for all intervals $I \in \mathcal{D}$ with $|I| \geq 2^{-r} |J|$, the distance from $J$ to the boundary of either child of $I$ is at least $|J|^{\epsilon} |I|^{1-\epsilon}$.

For $f \in L^2(\sigma)$, we set $P^w_{\text{good}} f = \sum_{I \text{ is } (\epsilon, r)\text{-good}} \Delta^q_I f$. The projection $P^w_{\text{good}} g$ is defined similarly. To make the two reductions below, one must make a random selection of grids, as is detailed in [9] and [29]. The use of random dyadic grids has been a basic tool since the foundational work of [14]–[16]. Important elements of the suppressed construction of random grids are the following.

1. It suffices to consider a single dyadic grid $\mathcal{D}$.
2. For any fixed $0 < \epsilon < 1/2$, we can choose an integer $r$ sufficiently large so that it suffices to consider $f$ such that $f = P^w_{\text{good}} f$, and likewise for $g \in L^2(w)$. Namely, it suffices to estimate the constant below, for an arbitrary dyadic grid $\mathcal{D}$,

$$|\langle H_\sigma f, g \rangle_w| \leq \mathcal{N}_{\text{good}} \|f\|_\sigma \|g\|_w,$$

where it is required that $f = P^\sigma_{\text{good}} \in L^2(\sigma)$ and $g = P^w_{\text{good}} \in L^2(w)$.

That the functions are good is, at some moments, an essential property. We suppress it in notation, however, taking care to emphasize in the text those places in which we appeal to the property of being good.

A reduction, using randomized dyadic grids, allows one the extraordinarily useful reduction in the next lemma. This is a well-known reduction, due to Nazarov, Treil, and Volberg, explained in full detail in the current setting in [18, Section 4]. Below, $\mathcal{H}$ is as in (1.5), the normalized sum of the $A_2$ and testing constants.

**Lemma 2.4**

For all sufficiently small $\epsilon$, and sufficiently large $r$, this holds. Suppose that for any
dyadic grid $\mathcal{D}$, such that no endpoint of an interval $I \in \mathcal{D}$ is a point mass for $\sigma$ or $w$, we have

$$\left| \langle H_\sigma P^\sigma_{\text{good}}, P^w_{\text{good}} g \rangle \right|_w \lesssim \mathcal{H} \| \sigma \| \| g \|_w. \quad (2.5)$$

Then, the same inequality holds without the projections $P^\sigma_{\text{good}}$ and $P^w_{\text{good}}$.

Inequality (2.5) should be understood as an inequality, uniform over the class of smooth truncations of the Hilbert transform. But, we can suppress this in the notation without causing confusion. The bilinear form only needs to be controlled for $(\epsilon, r)$-good functions $f$ and $g$, goodness being defined with respect to a fixed dyadic grid. Suppressing the notation, we write good for $(\epsilon, r)$-good, and it is always assumed that the dyadic grid $\mathcal{D}$ is fixed, and only good intervals are in the Haar support of $f$ and $g$, though is also suppressed in the notation.

3. The global-to-local reduction

The goal of this section is to reduce the analysis of the bilinear form in (2.5) to the local estimate, (3.4). It is sufficient to assume that $f$ and $g$ are supported on an interval $I^0$, by trivial use of the interval testing condition, we can further assume that $f$ and $g$ are of integral zero in their respective spaces. Thus, $f$ is in the linear span of (good) Haar functions $h^q_I$ for $I \subset I^0$, and similarly for $g$, and

$$\langle H_\sigma f, g \rangle_w = \sum_{I, J: I \subset I^0} \langle H_\sigma \Delta^q_I f, \Delta^w_J g \rangle_w.$$

The argument is independent of the choice of truncation that implicitly appears in the inner product above.

The double sum is broken into different summands. Many of the resulting cases are elementary, and we summarize these estimates as follows. Define the bilinear form

$$B^{\text{above}}(f, g) := \sum_{I: I \subset I^0} \sum_{J: J \subset I} \mathbb{E}^q_{I, J} \Delta^q_I f \cdot \langle H_\sigma I, \Delta^w_J g \rangle_w,$$

where here and throughout, $J \subset I$ means $J \subset I$ and $2^r |J| \leq |I|$. In addition, the argument of the Hilbert transform, $I_J$, is the child of $I$ that contains $J$, so that $\Delta^q_I f$ is constant on $I_J$. Define $B^{\text{below}}(f, g)$ in the dual fashion.

This set of dyadic grids that fail this condition have probability zero in standard constructions of the random dyadic grids.
Lemma 3.1
We have, with the notation of (1.5),
\[ |(H_\sigma f, g)_w - B_{\text{above}}(f, g) - B_{\text{below}}(f, g)| \lesssim \mathcal{H} \|f\|_\sigma \|g\|_w. \]

This is a common reduction in a proof of a $T1$ theorem, and in the current context, it only requires goodness of intervals and the $A_2$ condition. For a proof, one can consult [29] and [18]. The lemma is specifically phrased and proved in this way in [7, Section 8].

These definitions are needed to phrase the global-to-local reduction. The following definition depends upon the essential energy inequality (4.7) in Section 4.

Definition 3.2
Given any interval $F_0$, define $\mathcal{F}_{\text{energy}}(F_0)$ to be the maximal subintervals $F \subset F_0$ such that
\[ P(\sigma F_0, F)^2 E(w, F)^2 w(F) > 10C_0 \mathcal{H}^2 \sigma(F), \]
where $E(w, F)$ is defined in (4.6) and where $C_0$ is the constant in Proposition 4.8. We have $\sigma(\bigcup\{F : F \in \mathcal{F}(F_0)\}) \leq (\sigma/10)(F_0)$.

Definition 3.3
Let $I_0$ be an interval, and let $\mathcal{S}$ be a collection of disjoint intervals contained in $I_0$. A function $f \in L^2_0(I_0, \sigma)$ is said to be uniform (with respect to $\mathcal{S}$) if the following conditions are met.
1. Each energy stopping interval $F \in \mathcal{F}_{\text{energy}}(I_0)$ is contained in some $S \in \mathcal{S}$.
2. The function $f$ is constant on each interval $S \in \mathcal{S}$.
3. For any interval $I \subset I_0$ which is not contained in any $S \in \mathcal{S}$, $\mathbb{E}|f| \leq 1$.

We will say that $g$ is weakly adapted to a function $f$ uniform with respect to $\mathcal{S}$ if $J \subset S$ for some interval $S \in \mathcal{S}$ implies that $(g, h^w_J)_w = 0$. We will also say that $g$ is weakly adapted to $\mathcal{S}$.

The constant $\mathcal{L}$ is defined as the best constant in the local estimate
\[ |B_{\text{above}}(f, g)| \leq \mathcal{L}\{\sigma(I_0)^{1/2} + \|f\|_\sigma\} \|g\|_w, \quad (3.4) \]
where $f, g$ are of mean zero on their respective spaces, supported on an interval $I_0$. Moreover, $f$ is uniform and $g$ is weakly adapted to $f$. The inequality above is homogeneous in $g$, but not $f$, since the term $\sigma(I_0)^{1/2}$ is motivated by the bounded averages property of $f$. 
THEOREM 3.5 (Global-to-local reduction)
We have
\[ |B^{\text{above}}(f, g)| \lesssim \{H + \mathcal{L}\|f\|_\sigma\|g\|_w. \]
The same inequality holds for the dual form \(B^{\text{below}}(f, g)\).

A reduction of this type is a familiar aspect of many proofs of a \(T1\) theorem, proved by exploiting standard off-diagonal estimates for Calderón–Zygmund kernels, but in the current setting, it is a much deeper fact, a consequence of the functional energy inequality of Section 5. We make the following construction for an \(f \in L^2(I^0, \sigma)\), of \(\sigma\)-integral zero. Add \(I^0\) to \(\mathcal{F}\), and set \(\alpha_f(I^0) := \mathbb{E}_{I^0}^\sigma|f|\). In the inductive stage, if \(F \in \mathcal{F}\) is minimal, add to \(\mathcal{F}\) those maximal descendants \(F'\) of \(F\) such that \(F' \in \mathcal{F}_{\text{energy}}(F)\) or \(\mathbb{E}_{F'}^\sigma|f| \geq 10\alpha_f(F)\). Then define
\[
\alpha_f(F') := \begin{cases} 
\alpha_f(F) & \mathbb{E}_{F'}^\sigma|f| < 2\alpha_f(F), \\
\mathbb{E}_{F'}^\sigma|f| & \text{otherwise}.
\end{cases}
\]
If there are no such intervals \(F'\), the construction stops. We refer to \(\mathcal{F}\) and \(\alpha_f(\cdot)\) as Calderón–Zygmund stopping data for \(f\), following the terminology of [7, Definition 3.5]. Their key properties are collected here.

LEMMA 3.6
For \(\mathcal{F}\) and \(\alpha_f(\cdot)\) as defined above, the following hold.
1. The dyadic interval \(I_0\) is the maximal element of \(\mathcal{F}\).
2. For all \(I \in \mathcal{D}\), \(I \subset I^0\), we have \(\mathbb{E}_I^\sigma|f| \leq 10\alpha_f(\pi_\mathcal{F} I)\).
3. The datum \(\alpha_f\) is monotonic: If \(F, F' \in \mathcal{F}\) and \(F \subset F'\), then \(\alpha_f(F) \leq \alpha_f(F')\).
4. The collection \(\mathcal{F}\) is \(\sigma\)-Carleson in that
\[
\sum_{F \in \mathcal{F} : F \subset S} \sigma(F) \leq 2\sigma(S), \quad S \in \mathcal{D}. \tag{3.7}
\]
5. We have the inequality
\[
\left\| \sum_{F \in \mathcal{F}} \alpha_f(F) \cdot F \right\|_\sigma \lesssim \|f\|_\sigma. \tag{3.8}
\]

Proof
The first three properties are immediate from the construction. The fourth, the \(\sigma\)-Carleson property is seen this way. It suffices to check the property for \(S \in \mathcal{F}\).
Now, the $\mathcal{F}$-children can be in $\mathcal{F}_{\text{energy}}(S)$, which satisfy
\[ \sum_{F' \in \mathcal{F}_{\text{energy}}(S)} \sigma(F') \leq \frac{1}{10} \sigma(S). \]

Otherwise, note that by choice of $\alpha_f(\cdot)$, we have $\mathbb{E}_{S}^g |f| \leq 2\alpha_f(S)$. These intervals $F'$ satisfy $\mathbb{E}_{F'}^g |f| \geq 10\alpha_f(S) \geq 5\mathbb{E}_{S}^g |f|$. These intervals satisfy the display above with $1/10$ replaced by $1/5$. Hence, (3.7) holds.

For the final property, let $\mathcal{G} \subset \mathcal{F}$ be the subset at which the stopping values change. If $F \in \mathcal{F} - \mathcal{G}$, and $G$ is the $\mathcal{G}$-parent of $F$, then $\alpha_f(F) = \alpha_f(G)$. Set
\[ \Phi_G := \sum_{F \in \mathcal{F} : \pi_G F = G} F. \]

Define $G_k := \{ \Phi_G \geq 2^k \}$, for $k = 0, 1, \ldots$. The $\sigma$-Carleson property implies integrability of all orders in $\sigma$-measure of $\Phi_G$. Using the third moment, we have $\sigma(G_k) \lesssim 2^{-3k} \sigma(G)$. Then, estimate
\[
\left\| \sum_{F \in \mathcal{F}} \alpha_f(F) \cdot F \right\|_{\sigma}^2 = \left\| \sum_{G \in \mathcal{G}} \alpha_f(G) \Phi_G \right\|_{\sigma}^2 \leq \left\| \sum_{k=0}^{\infty} (k+1)^{1-1} \sum_{G \in \mathcal{G}} \alpha_f(G) 2^k 1_{G_k} \right\|_{\sigma}^2 \lesssim \sum_{k=0}^{\infty} (k+1)^2 \left\| \sum_{G \in \mathcal{G}} \alpha_f(G) 2^k 1_{G_k}(x) \right\|_{\sigma}^2 \leq \sum_{G \in \mathcal{G}} \alpha_f(G)^2 \sigma(G) \lesssim \|Mf\|_{\sigma}^2 \lesssim \|f\|_{\sigma}^2.
\]

Note that we have used Cauchy–Schwarz in $k$ at the step marked by an *. In the step marked with **, for each point $x$, the nonzero summands are a (super)geometric sequence of scalars, so the square can be moved inside the sum. Finally, we use the estimate on the $\sigma$-measure of $G_k$, and compare to the maximal function $Mf$ to complete the estimate.

\[ P^\alpha f := \sum_{I \in \mathcal{D} : \pi_I I = F} \Delta^\alpha f, \quad F \in \mathcal{F}, \]

\[ \Box \]
and similarly for $Q^u_F$, but rather than use $\pi_{\mathcal{F}} J$ in the definition, we use $\pi_{\mathcal{F}} J$, defined to be the minimal $F \in \mathcal{F}$ with $J \subseteq F$. Without this alternate definition, some delicate case analysis would be forced upon us. The inequality (3.8) allows us to estimate

$$
\sum_{F \in \mathcal{F}} \{\alpha_f(F)\sigma(F)^{1/2} + \|P^\sigma_F f\|_\sigma\} \|Q^u_F g\|_w
\leq \left[\sum_{F \in \mathcal{F}} \{\alpha_f(F)\sigma(F)^2 + \|P^\sigma_F f\|_\sigma^2\} \times \sum_{F \in \mathcal{F}} \|Q^u_F g\|_w^2\right]^{1/2}
\lesssim \|f\|_\sigma\|g\|_w.
$$

(3.9)

We will refer to this as the quasiothogonality argument, and we remark that it only requires orthogonality of the projections $Q^u_F g$. It is very useful.

**Lemma 3.10**

We have

$$
|B^{\text{above}}(f, g) - B^{\text{above}}_{\mathcal{F}}(f, g)| \lesssim \mathcal{H}\|f\|_\sigma\|g\|_w,
$$

where $B^{\text{above}}_{\mathcal{F}}(f, g) := \sum_{F \in \mathcal{F}} B^{\text{above}}(P^\sigma_F f, Q^u_F g)$.

**Proof**

We apply the functional energy inequality of Section 5. Observe that $f = \sum_{F \in \mathcal{F}} P^\sigma_F f$ and that

$$
\sum_{J: J \subseteq I_0} \Delta^w_J g = \sum_{F \in \mathcal{F}} Q^u_F g.
$$

From the definition of $B^{\text{above}}(f, g)$, we can assume that $g$ equals the sum above. Therefore,

$$
B^{\text{above}}(f, g) = \sum_{F' \in \mathcal{F}} \sum_{F \in \mathcal{F}} B^{\text{above}}(P^\sigma_{F'} f, Q^u_F g).
$$

In the sum above, we can also add the restriction that $F' \cap F \neq \emptyset$, for otherwise $B^{\text{above}}(P^\sigma_{F'} f, Q^u_F g) = 0$. For a pair of intervals $J \in I_J$, note that this implies that $J \subseteq \pi_{\mathcal{F}} I$; that is, $\pi_{\mathcal{F}} J \subset \pi_{\mathcal{F}} I$. Therefore, we can add the restriction $F \subset F'$. The case of $F' = F$ is the definition of $B^{\text{above}}_{\mathcal{F}}(f, g)$, so that it suffices to estimate

$$
\sum_{F, F' \in \mathcal{F}} B^{\text{above}}(P^\sigma_{F'} f, Q^u_F g).
$$

(3.11)
Observe that the functions $g_F := Q^{w}_F g$ are $\mathcal{F}$-adapted in the sense of Definition 5.1, and by construction $\mathcal{F}$ satisfies the Carleson measure condition (3.7). We take these steps to apply the functional energy inequality. The argument of the Hilbert transform is $I_F$, the child of $I$ that contains $F$. Write $I_F = F + (I_F - F)$, and use linearity of $H_\sigma$. Note that by the standard martingale difference identity and the construction of stopping data,

$$
\left| \sum_{I : I \supseteq F} \mathbb{E}^q_{I_F} \Delta^q_I f \right| \lesssim \alpha_f (F), \quad F \in \mathcal{F}.
$$

Hence, invoking interval testing,

$$
\left| \sum_{F \in \mathcal{F}} \sum_{I : I \supseteq F} \mathbb{E}^q_{I_F} \Delta^q_I f \cdot \langle H_\sigma F, g_F \rangle_w \right| \lesssim \sum_{F \in \mathcal{F}} \alpha_f (F) \left| \langle H_\sigma F, g_F \rangle_w \right|
\lesssim \mathcal{H} \sum_{F \in \mathcal{F}} \alpha_f (F) \sigma (F)^{1/2} \| g_F \|_w.
$$

Quasiorthogonality bounds this last expression.

For the second expression, when the argument of the Hilbert transform is $I_F - F$, first note that

$$
\left| \sum_{I : I \supseteq F} \mathbb{E}^q_{I_F} \Delta^q_I f \cdot (I_F - F) \right| \lesssim \Phi := \sum_{F' \in \mathcal{F}} \alpha_f (F') \cdot F', \quad F \in \mathcal{F}.
$$

Therefore, by the definition of $\mathcal{F}$-adapted, the monotonicity property (4.3) applies, and yields

$$
\left| \sum_{I : I \supseteq F} \mathbb{E}^q_{I_F} \Delta^q_I f \cdot \langle H_\sigma (I_F - F), g_F \rangle_w \right| \lesssim \sum_{J \in \mathcal{J}^*(F)} P (\Phi \sigma, J) \left( \frac{x}{|J|}, J \overline{g}_F \right)_w, \quad F \in \mathcal{F}.
$$

Here, $\mathcal{J}^*(F)$ are the maximal good intervals $J \subseteq F$, and $\overline{g}_F := \sum_{J \in \mathcal{J}(F): J \subseteq F} |\hat{g}(J)| \cdot h^w_F$, so that every term has a positive inner product with $x$. The sum over $F \in \mathcal{F}$ of this last expression is controlled by functional energy, and by the property that $\| \Phi \|_{\sigma} \lesssim \| f \|_{\sigma}$. This completes the bound for (3.11).

\begin{proof}[Proof of Theorem 3.5]
By Lemma 3.10, it remains to control $B_{\mathcal{F}}^{\text{above}} (f, g)$. Keeping the quasiorthogonality argument in mind, we see that appropriate control on the individual summands is enough to control it. For each $F \in \mathcal{F}$, let $\mathcal{S}_F$ be the $\mathcal{F}$-children of $F$. Observe that the function

$$
(C \alpha_f (F))^{-1} P^q_F f
$$

(3.12)
is uniform on \( F \) with respect to \( \mathcal{S}_F \), for an appropriate absolute constant \( C \). Moreover, the function \( Q^w_F g \) does not have any interval \( J \) in its Haar support strongly contained in an interval \( S \subseteq \mathcal{S}_F \). That is, it is weakly adapted to the function in (3.12). Therefore, by assumption,

\[
\left| B^{\text{above}}(P^\sigma_F f, Q^w_F g) \right| \leq \mathcal{L}\{\alpha_F(F)\sigma(F)^{1/2} + \| P^\sigma_F f \|_\sigma \} \| Q^w_F g \|_w.
\]

The sum over \( F \in \mathcal{F} \) of the right-hand side is bounded by the quasiorthogonality argument of (3.9).

### 4. Energy, monotonicity, and Poisson

Our theorem (Theorem 1.2) is particular to the Hilbert transform, and so depends upon special properties of it. They largely extend from the fact that the derivative of \(-1/y\) is positive. The following monotonicity property for the Hilbert transform was observed in [7, Lemma 5.8], and is basic to the analysis of the functional energy inequality.

**Lemma 4.1 (Monotonicity property)**

Let \( K \supseteq I \) be two intervals, and assume that \( \sigma \) does not have point masses at the end point of \( I \). Then, for any function \( g \in L^2(I, w) \), with \( w \)-integral zero, and \( \beta > 2|K| \),

\[
P(\sigma \cdot (K - I), I) \left( \frac{\chi}{|I|}, \overline{g} \right)_w \lesssim \liminf_{\alpha \downarrow 0} \{H_{\alpha, \beta}(\sigma(K - I)), \overline{g}\}_w. \tag{4.2}
\]

Here, \( \overline{g} = \sum_i |\widehat{g}(J_i)| h^w_{J_i} \) is a Haar multiplier applied to \( g \). If \( J \) is a good interval, \( J \subseteq I \), then, for function \( g \in L^2(J, w) \), with \( w \)-integral zero, and signed measures \( \nu \) and \( \mu \) supported on \( K - I \), with \( |\nu| \leq \mu \), we have

\[
\sup_{0 < \alpha < \beta} \left| \langle H_{\alpha, \beta} \nu, g \rangle_w \right| \lesssim P(\mu, J) \left( \frac{\chi}{|J|}, \overline{g} \right)_w. \tag{4.3}
\]

The truncations enter into the formulation of the lemma, since they play a notable role here. We need this preparation.

**Lemma 4.4**

Let \( I \) and \( J \) be two intervals which share an endpoint \( a \), at which neither \( \sigma \) nor \( w \) have a point mass. Then,

\[
\sup_{0 < \alpha < \beta} \left| \langle H_{\alpha, \beta} \sigma I, J \rangle_w \right| \lesssim \mathcal{A}_{2}^{1/2} \sqrt{\sigma(I)w(J)}. \tag{4.5}
\]

**Proof**

If \( |I| \approx |J| \), this inequality is the weak boundedness principle of [9, Section 2.2]. So, let us assume that \( 10|I| < |J| \). Then, it remains to bound
\[
\left| \left[ H_{\alpha, \beta} \sigma I, (J \setminus 10I) \right]_w \right| \leq \sum_{n=1}^{\infty} \frac{\sigma(I)w(J \cap ((n+1)I \setminus nI))}{n|I|} \\
\leq \frac{\sigma(I)}{|I|^{1/2}} P(w, I)^{1/2} w(J)^{1/2} \lesssim A_2^{1/2} \sqrt{\sigma(I)w(J)}.
\]

This depends upon obvious kernel bounds, and an application of Cauchy–Schwarz to derive the Poisson term above. \hfill \Box

**Proof of Lemma 4.1**

By linearity, it suffices to prove (4.2) in the case of \( g = h^w_I \). The point is to separate the supports of the functions involved. Since \( I \) does not have a point mass at the end point of \( I \), we have \( \sigma(\lambda I \setminus I) \downarrow 0 \) as \( \lambda \downarrow 1 \). It follows that we can fix a \( \lambda > 1 \) sufficiently small so that \( P(\sigma(K - I), I) \simeq P(\sigma(K - \lambda I), I) \), and one more condition that we will come back to. Then, for \( 0 < \alpha < (1/2)(\lambda - 1)|I| \), we estimate as below, where \( x_I \) is the center of \( I \),

\[
\left\langle H_{\alpha, \beta}(\sigma(K - \lambda I)), h^w_I \right\rangle_w \\
= \int_{K-\lambda I} \int_I \left\{ K_{\alpha, \beta}(y - x) - K_{\alpha, \beta}(y - x_I) \right\} h^w_I(x)w(dx)\sigma(dy) \\
= \int_{K-\lambda I} \int_I \frac{x - x_I}{(y - x)(y - x_I)} h^w_I(x)w(dx)\sigma(dy) \\
\gtrsim P(\sigma(K - I), I) \left\langle \frac{x - x_I}{|I|}, h^w_I \right\rangle_w.
\]

We have subtracted the term, since \( h^w_I \) has integral zero, then we applied (2.3) with \( C_{x, x_J, y} = 1 \), as follows from our choices of \( \alpha \) and \( \beta \). Then, note that \( (x - x_J)h^w_I \geq 0 \), so that we can pull out the Poisson term. The last line follows by our selection of \( \lambda \) sufficiently close to 1. Then, the last condition needed is to select \( \lambda \) sufficiently close to 1 that, in view of (4.5),

\[
\sup_{\alpha, \beta} \left| \left\langle H_{\alpha, \beta}(\lambda I \setminus I), h^w_I \right\rangle_w \right| \lesssim A_2^{1/2} \sqrt{\sigma(\lambda I \setminus I)} < c P(\sigma(K - I), I) \left\langle \frac{x - x_I}{|I|}, h^w_I \right\rangle_w.
\]

In the last line, \( c > 0 \) is an absolute constant. This completes the proof of (4.2).

Turn to (4.3). The estimate (2.3) applies:

\[
\left| \left\langle H_{\alpha, \beta} v, g \right\rangle_w \right| = \left| \int_{K-I} \int_J \left\{ K_{\alpha, \beta}(y - x) - K_{\alpha, \beta}(y - x_J) \right\} h^w_J(x)w(dx)v(dy) \right| \\
= \left| \int_{K-I} \int_J C_{x, x_J, y} \frac{(x - x_J)}{(y - x)(y - x_J)} h^w_J(x)w(dx)v(dy) \right|.
\]
But recall that $0 \leq C_{x,xJ,y} \leq 4$ and that it equals 1 for $\alpha$ sufficiently small. Moreover, $y - x$ and $y - x_J$ have the same sign, and $(x - x_J)h_{J}^{w}(x) \geq 0$. So an upper bound is obtained by passing from $v$ to $\mu$:

$$\left|\langle H_{\alpha,\beta}v, g \rangle \right|_{w} \leq \int_{K-I} \int_{J} \frac{(x - x_J)}{(y - x)(y - x_J)} h_{J}^{w}(x) w(dx) \mu(dy)$$

$$\simeq P(\mu, J) \left| \frac{x}{|J|} , h_{J}^{w} \right|_{w} . \square$$

The concept of energy is fundamental to the subject. For interval $I$, define

$$E(w, I)^2 := \mathbb{E}_{I} \frac{w(dx)w(dx') (x - x')^2}{|I|^2} \sum_{J \subseteq I} \left| \frac{x}{|J|} , h_{J}^{w} \right|_{w}^2 . \quad (4.6)$$

Now, consider the energy constant, the smallest constant $\mathcal{E}$ such that this condition holds, as presented or in its dual formulation. For all dyadic intervals $I_0$, all partitions $\mathcal{P}$ of $I_0$ into dyadic intervals, we have

$$\sum_{I \in \mathcal{P}} P(\sigma I_0, I)^2 E(w, I)^2 w(I) \leq \mathcal{E}^2 \sigma(I_0) . \quad (4.7)$$

This was shown in [9, Proposition 2.11].

**Proposition 4.8**

**For a finite constant $C_0$,**

$$\mathcal{E}^2 \leq C_0 \{ A_2^{1/2} + T \}^2 = C_0 \mathcal{H}^2 .$$

We will always estimate $\mathcal{E}$ by $\mathcal{H}$. The proof is recalled here.

**Proof**

It suffices to consider the case of finite partitions $\mathcal{P}$ of $I$. We first prove a version of the energy inequality with holes in the argument of the Poisson. It follows from (4.2) that we can fix $0 < \alpha < \beta$ such that

$$P(\sigma(I_0 - I), I)^2 E(w, I)^2 w(I) \lesssim \left\| H_{\alpha,\beta}(\sigma(I_0 - I)) \right\|_{L^2(I, \sigma)}^2 , \quad I \in \mathcal{P} .$$

Then, using linearity and interval testing, we have

$$\sum_{I \in \mathcal{P}} \left\| H_{\alpha,\beta}(\sigma \cdot I_0) \right\|_{L^2(I, \sigma)}^2 \lesssim \left\| H_{\alpha,\beta}(\sigma \cdot I_0) \right\|_{L^2(I, \sigma)}^2 \lesssim \mathcal{H}^2 \sigma(I_0) .$$
and
\[ \sum_{I \in \mathcal{P}} \left\| H_{\alpha, \beta}(\sigma \cdot I) \right\|_{L^2(I, \sigma)}^2 \lesssim \mathcal{H}^2 \sum_{I \in \mathcal{P}} \sigma(I) \lesssim \mathcal{H}^2 \sigma(I_0). \]

Then, by the $A_2$ bound, we have $P(\sigma \cdot I, I)^2 E(w, I)^2 w(I) \lesssim \sigma(I)$, which we can sum over the partition. This completes the proof.

One should keep in mind that the concept of energy is related to the tails of the Hilbert transform. The energy inequality, and its multiscale extension to the functional energy inequality, show that the control of the tails is very subtle in this problem.

We also need the following elementary Poisson estimate from [29]; used occasionally in this argument, it is crucial to the proof of Lemma 3.1.

**Lemma 4.9**
Suppose that $J \Subset I \subset I_0$, and that $J$ is good. Then
\[ |J|^{2\varepsilon} P(\sigma(I_0 - I), J) \lesssim |I|^{2\varepsilon} P(\sigma(I_0 - I), I). \]

**Proof**
We have $\text{dist}(J, I_0 - I) \geq |J|^\varepsilon |I|^{1-\varepsilon}$, so that for any $x \in I_0 - I$, we have
\[ \frac{|J|^{2\varepsilon}}{(|J| + \text{dist}(x, J))^2} \lesssim \frac{|I|^{2\varepsilon}}{(|I| + \text{dist}(x, I))^2}. \]

Integrating this last expression, it follows that
\[ |J|^{2\varepsilon} P(\sigma \cdot (I_0 - I), J) = |J|^{2\varepsilon} \int_{I_0 - I} \frac{|J|}{(|J| + \text{dist}(x, J))^2} d\sigma \lesssim |I|^{2\varepsilon} \int_{I_0 - I} \frac{1}{(|J| + \text{dist}(x, J))^2} d\sigma. \]
And this proves the inequality.

5. **The functional energy inequality**
We state an important multiscale extension of the energy inequality (4.7).

**Definition 5.1**
Let $\mathcal{F}$ be a collection of dyadic intervals. A collection of (good) functions $\{g_F\}_{F \in \mathcal{F}}$ in $L^2(w)$ is said to be $\mathcal{F}$-adapted if, for all $F \in \mathcal{F}$, the Haar support of the function $g_F$ is contained in $\{J : \pi_H J = F\}$. 
Definition 5.2
Let $F$ be the smallest constant in the inequality below, or its dual form. The inequality holds for all nonnegative $h \in L^2(\sigma)$, all $\sigma$-Carleson collections $F$, and all $F$-adapted collections $\{g_F\}_{F \in F}$:

$$
\sum_{F \in F} \sum_{J^* \in \mathcal{G}^*(F)} P(h\sigma, J^*) \left| \left( \frac{x}{|J^*|}, g_F J^* \right) \right|_w \leq F \|h\|_\sigma \left[ \sum_{F \in F} \|g_F\|_w^2 \right]^{1/2}.
$$

Here $\mathcal{G}^*(F)$ consists of the maximal good intervals $J \Subset F$. Note that the estimate is universal in $h$ and $F$, separately.

This constant was identified in [7], and is herein shown to be necessary from the $A_2$ and interval testing inequalities. Recall the definition of $\mathcal{H}$ in (1.5).

**Theorem 5.3**

Assume that $F$ satisfies (3.7); then, $F \lesssim \mathcal{H}$.

The first step in the proof is the domination of the constant $F$ by the best constant in a certain two-weight inequality for the Poisson operator, with the weights being determined by $w$ and $\sigma$ in a particular way. This is the decisive step, since there is a two-weight inequality for the Poisson operator proved by one of us in [27, Theorem 2]. It reduces the full norm inequality to simpler testing conditions, which are in turn controlled by the $A_2$ and Hilbert transform testing conditions.

5.1. The two-weight Poisson inequality
Consider the weight

$$
\mu \equiv \sum_{F \in F} \sum_{J \in \mathcal{G}^*(F)} \left\| P_{F,J}^w \frac{x}{|J|} \right\|_w^2 \cdot \delta_{(x_J, |J|)}.
$$

Here, $P_{F,J}^w := \sum_{J': J \Subset J, x_F J = F} \Delta_{J'}^w$. We can replace $x$ by $x - c$ for any choice of $c$ we wish; the projection is unchanged. And $\delta_q$ denotes a Dirac unit mass at a point $q$ in the upper half-plane $\mathbb{R}^2_+$. We prove the two-weight inequality for the Poisson integral

$$
\left\| \mathbb{P}(h\sigma) \right\|_{L^2(\mathbb{R}^2_+, \mu)} \lesssim \mathcal{H} \|h\|_\sigma,
$$

for all nonnegative $h$. Above, $\mathbb{P}(-)$ denotes the Poisson extension operator to the upper half-plane, so that in particular

$$
\left\| \mathbb{P}(h\sigma) \right\|_{L^2(\mathbb{R}^2_+, \mu)}^2 = \sum_{F \in F} \sum_{J \in \mathcal{G}^*(F)} \mathbb{P}(h\sigma) \left( x_J, |J| \right)^2 \left\| P_{F,J}^w \frac{x}{|J|} \right\|_w^2,
$$

where $x_J$ is the center of the interval $J$. The proof of Theorem 5.3 follows by duality.
Phrasing things in this way brings a significant advantage. The characterization of the two-weight inequality for the Poisson operator (see [27]) reduces the full norm inequality above to these testing inequalities. For any dyadic interval \( I \in \mathcal{D} \) we have

\[
\int_{\mathbb{R}_+^2} \mathbb{P}(\sigma \cdot I)^2 \, d\mu(x,t) \lesssim \mathcal{H}^2 \sigma(I),
\]

where \( \mathcal{H} \) is the Haar space and \( \sigma \) is the weight function.

\[
\int_{\mathbb{R}} \mathbb{P}^*(t I \mu)^2 (dx) \lesssim \mathcal{A}_2 \int_I t^2 \, d\mu(x,t),
\]

where \( \mathcal{A}_2 \) is the constant for the two-weight inequality with \( \mathcal{A}_2 = \frac{1}{2\mathcal{A}_2} \).

Remark 5.6

A gap in the proof of the Poisson inequality in [27, p. 542] can be fixed as in [28] or [8].

5.2. The Poisson testing inequality: The core

This section is concerned with a part of inequality (5.4). Restrict the integral on the left-hand side to the set \( \tilde{I} \subset \mathbb{R}_+^2 \):

\[
\int_{\tilde{I}} \mathbb{P}(\sigma \cdot I)^2 \, d\mu(x,t) \lesssim \mathcal{H}^2 \sigma(I).
\]

Since \((x_J, |J|) \in \tilde{I}\) if and only if \( J \subset I \), we have

\[
\int_{\tilde{I}} \mathbb{P}(\sigma \cdot I)(x,t)^2 \, d\mu(x,t) = \sum_{F \in \mathcal{F}} \sum_{J \in \mathcal{J}^*(F): J \subset I} \mathbb{P}(\sigma \cdot I)(x_J, |J|)^2 \left\| P_{F,J}^w \frac{x}{|J|} \right\|_w^2.
\]

For each \( J \),

\[
\left\| P_{F,J}^w \frac{x}{|J|} \right\|_w^2 \leq \int_J \left| \frac{x - \mathcal{E}^w_J x}{|J|} \right|^2 \, dw(x) = 2E(w, J)^2 w(J) \leq 2w(J). \tag{5.7}
\]

Let \( \mathcal{F}_0 \) be the maximal \( F \in \mathcal{F} \) which are strictly contained in \( I \), and let \( \mathcal{J}^{dy} \) be those dyadic \( J \) such that \((x_J, |J|) \) is in the support of \( \mu \), but has no parent in \( \mathcal{F}_0 \).
These intervals are necessarily disjoint. Observe that by (5.7) and the energy inequality,

$$\sum_{J \in \mathcal{F}} \mathbb{P}(\sigma F) (x_J, |J|) \mu(x_J, |J|) \lesssim \sum_{J \in \mathcal{F}} P(\sigma \cdot F, J)^2 E(w, J)^2 w(J)$$

$$\lesssim \mathcal{H}^2 \sigma(F). \quad (5.8)$$

We claim that

$$\sum_{F \in \mathcal{F}_0} \int_{\hat{F}} \mathbb{P}(\sigma(I \setminus F))(x, t)^2 \, d\mu(x, t) \lesssim \mathcal{H} \sigma(I). \quad (5.9)$$

This is sufficient, since

$$\int_{\hat{F}} \mathbb{P}(\sigma \cdot I)(x, t)^2 \, d\mu(x, t)$$

$$\lesssim \text{LHS}(5.8) + \text{LHS}(5.9) + \sum_{F \in \mathcal{F}_0} \int_{\hat{F}} \mathbb{P}(\sigma \cdot F)(x, t)^2 \, d\mu(x, t)$$

$$\lesssim \mathcal{H}^2 \sigma(I) + \sum_{F \in \mathcal{F}_0} \int_{\hat{F}} \mathbb{P}(\sigma \cdot F)(x, t)^2 \, d\mu(x, t).$$

The individual terms in the last sum are set up for a recursive application of this inequality. Due to the Carleson condition (3.7), this recursion will finish the proof.

It remains to prove (5.9), which is another instance of the energy inequality. For an interval $F_0 \in \mathcal{F}_0$, and $F \in \mathcal{F}$ strictly contained in $F_0$, each interval $J \in \mathcal{F}^*(F)$ is contained in some $J_0 \in \mathcal{F}^*(F_0)$. Then, the intervals $F \in \mathcal{F}$ are not good, but $J$ and $J_0$ are good, hence

$$\mathbb{P}(\sigma(I \setminus F_0))(x_J, |J|)^2 \mu(x_J, |J|) = \left[ \int_{I \setminus F_0} \frac{|J|}{|J| + |x - x_J|^2} \right]^2 \| P_{F, J}^{w} \frac{x}{|J|} \|^2_{w}$$

$$= \left[ \int_{I \setminus F_0} \frac{1}{|J| + |x - x_J|^2} \right]^2 \| P_{F, J}^{w} \frac{x}{|J|} \|^2_{w}$$

$$\lesssim \left[ \int_{I \setminus F_0} \frac{|J_0|}{|J_0| + |x - x_J|^2} \right]^2 \| P_{F, J}^{w} \frac{x}{|J_0|} \|^2_{w}.\$$

This follows from goodness. For $x \in I \setminus F_0$,

$$|J|^2 + |x - x_J|^2 \geq |x - x_J|^2 \geq |x - x_J|^2 \geq |J_0|^2 |F_0|^{1-\epsilon}.$$

But then, we can add the projections $P_{F, J}^{w}$, due to orthogonality, and use (5.7) again to see that
\[
\sum_{F \in \mathcal{F}} \sum_{J \in \mathcal{J}^*(F) \cap F} \mathbb{P}(\sigma(I \setminus F_0))(x_J, |J|)^2 \mu(x_J, |J|)
\leq \mathbb{P}(\sigma \cdot I)(x_{J_0}, |J_0|)^2 \sum_{F \in \mathcal{F}} \sum_{J \in \mathcal{J}^*(F) \cap F} \left\| P_{F,J} x_{|J|} \right\|_w^2
\leq \mathbb{P}(\sigma \cdot I)(x_{J_0}, |J_0|)^2 E(w, J_0)^2 w(J_0).
\]
The sum over \( F_0 \in \mathcal{F}_0 \), and \( J_0 \in \mathcal{J}^*(F_0) \) is controlled by the energy inequality. This completes the proof of (5.9).

5.3. The Poisson testing inequality: The remainder

Now we turn to proving the following estimate for the global part of the first testing condition (5.4):

\[
\int_{\mathbb{R}^2_+ - \mathcal{I}} \mathbb{P}(\sigma \cdot I)^2 \, d\mu \lesssim A_2 \sigma(I).
\]

Decompose the integral on the left-hand side into four terms. With \( F_J \) the unique \( F \in \mathcal{F} \) with \( J \in \mathcal{J}^*(F) \), and using (5.7),

\[
\int_{\mathbb{R}^2_+ - \mathcal{I}} \mathbb{P}(\sigma \cdot I)^2 \, d\mu = \sum_{J: (x_J, |J|) \in \mathbb{R}^2_+ - \mathcal{I}} \mathbb{P}(\sigma \cdot I)(x_J, |J|)^2 \left\| P_{F,J} x_{|J|} \right\|_w^2 \leq \sum_{J: J \cap 3I = \emptyset} + \sum_{J: J \subset 3I - I} + \sum_{J: |J| > |I|} + \sum_{J: |J| \neq |I|} \mathbb{P}(\sigma \cdot I)(x_J, |J|)^2 w(J) = A + B + C + D.
\]

Decompose term \( A \) according to the length of \( J \) and its distance from \( I \), to obtain

\[
A \lesssim \sum_{n=0}^{\infty} \sum_{k=1}^{\infty} \sum_{J: J \subset 3^{k+1}I - 3^k I \setminus |J| = 2^{-n}|I|} \left( \frac{2^{-n}|I|}{\operatorname{dist}(J,I)^2} \right)^2 \sigma(I)^2 w(J)
\]

\[
\lesssim 2^{-2n} \sum_{n=0}^{\infty} \sum_{k=1}^{\infty} \frac{|I|^2 \sigma(I) w(3^{k+1}I - 3^k I) \sigma(I)}{|3^k I|^4}
\]

\[
2^{-2n} \sum_{n=0}^{\infty} \sum_{k=1}^{\infty} \frac{|I|^2 \sigma(I) w(3^{k+1}I - 3^k I) \sigma(I)}{|3^k I|^2} \sigma(I) \lesssim A_2 \sigma(I).
\]
Decompose term $B$ according to the length of $J$ and then use the Poisson inequality (4.10), available to use because of goodness of intervals $J$. We then obtain

$$B \lesssim \sum_{n=0}^{\infty} \sum_{J: J \subset 3I-I, |J|=2^{-n}} 2^{-n(2-4\epsilon)} \frac{\sigma(I)^2}{|I|^2} w(J)$$

$$\lesssim \sum_{n=0}^{\infty} 2^{-n(2-4\epsilon)} \frac{\sigma(3I)w(3I)}{|3I|^2} \sigma(I) \lesssim A_2 \sigma(I).$$

For term $C$, for $n = 1, 2, \ldots$, set $J_n$ to be those good dyadic intervals $J$ with $|J| > |I|$, $J \cap I = \emptyset$ and

$$(n-1)|J| \leq \text{dist}(I, J) < n|J|.$$  

These intervals have bounded overlaps. Indeed, suppose that $J_1 \ni \cdots \ni J_r$ are all members for $J_1$. Then, by goodness,

$$\text{dist}(J_1, I) \geq \text{dist}(J_r, I) \geq (n-1)2^r |J_1| + \text{dist}(J_1, \partial J_r) \geq \{(n-1)2^r + 2^{r(1-\epsilon)}\}|J_1|,$$

which is a contradiction to membership in $J_n$. Restricting the sum to intervals in $J_n$, we have

$$\sum_{J \in J_n} \mathbb{P}(\sigma \cdot I)(x_J, |J|)^2 w(J) \lesssim \sigma(I)^2 \sum_{J \in J_n} \frac{w(J)}{n^4 |J|^2}$$

$$\lesssim \frac{\sigma(I)^2}{|I|} \sum_{J \in J_n} \frac{w(J) \cdot |I|}{n^4 |J|^2}$$

$$\lesssim \frac{\sigma(I)}{n^2} \cdot \frac{\sigma(I)}{|I|} P(w, I) \lesssim A_2 \frac{\sigma(I)}{n^2}.$$  

And this is summable in $n \in \mathbb{N}$.

In the last term $D$, all the intervals $J$ contain $I$. Note that

$$\sum_{J: J \not\subset I} \mathbb{P}(\sigma \cdot I)(x_J, |J|)^2 w(J) \lesssim \sigma(I)^2 \sum_{J: J \not\subset I} \frac{w(J)}{|J|^2}$$

$$\lesssim \sigma(I) \cdot \frac{\sigma(I)}{|I|} \sum_{J: J \not\subset I} \frac{w(J) \cdot |I|}{|J|^2}$$

$$\lesssim \sigma(I) \cdot \frac{\sigma(I)}{|I|} P(w, I) \lesssim A_2 \sigma(I).$$
5.4. The dual Poisson testing inequality
We are considering (5.5). Note that there is a power of $t$ on both sides and that the expressions on the two sides of this inequality are

$$\int \mu(dx, dt) = \sum_{F \in \mathcal{F}} \sum_{J \in \mathcal{J}(F)} \|P_{F,J}x\|_w^2,$$

$$\mathbb{P}^*(t\hat{\mu})(x) = \sum_{F \in \mathcal{F}} \sum_{J \in \mathcal{J}(F)} \frac{\|P_{F,J}x\|_w^2}{|J|^2 + |x - x_J|^2}.$$

We are to dominate $\|\mathbb{P}^*(t\hat{\mu})\|_o^2$ by the first expression above. The squared norm will be the sum over integers $s$ of $T_s$ below, in which the relative lengths of $J$ and $J'$ are fixed by $s$. Suppressing the requirement that $J, J' \subset I$,

$$T_s := \sum_{F \in \mathcal{F}} \sum_{J \in \mathcal{J}(F)} \sum_{J' \in \mathcal{J}(F)} \sum_{J' \in \mathcal{J}(F)} \left( \int \frac{\|P_{F,J}x\|_w^2}{|J|^2 + |x - x_J|^2} \cdot \frac{\|P_{F',J'}x\|_w^2}{|J'|^2 + |x - x_{J'}|^2} \right) d\sigma,$$

$$\leq M_s \sum_{F \in \mathcal{F}} \sum_{J \in \mathcal{J}(F)} \|P_{F,J}x\|_w^2,$$

where

$$M_s \equiv \sup_{F \in \mathcal{F}} \sup_{J \in \mathcal{J}(F)} \sum_{J' \in \mathcal{J}(F)} \int \frac{1}{|J|^2 + |x - x_J|^2} \cdot \frac{w(J') \cdot |J'|^2}{|J'|^2 + |x - x_{J'}|^2} d\sigma.$$

The estimate (5.7) has been used in the definition of $M_s$. We claim the term $M_s$ is at most a constant times $A_2^{-2s}$, and it is here that the full Poisson $A_2$ condition is used.

Fix $J$, and let $n \in \mathbb{N}$ be the integer chosen so that $(n-1)|J| \leq \text{dist}(J, J') \leq n|J|$. Estimate the integral in the definition of $M_s$ by

$$\frac{w(J')}{|J'|} \int \frac{|J'|^2}{|J|^2 + |x - x_J|^2} \cdot \frac{|J|}{|J'|^2 + |x - x_{J'}|^2} d\sigma \lesssim A_2^{-2s}.$$

This estimate is adequate for $n = 0, 1, 2$. Then estimate the sum over $J'$ as

$$\sum_{F' \in \mathcal{F}} \sum_{J' \in \mathcal{J}(F'); |J'| = 2^{-s}|J|} \frac{2^{-2s}}{2^{-s}} \lesssim 2^{-s},$$

because the relative lengths of $J$ and $J'$ are fixed, and each $J'$ is in at most one $\mathcal{J}(F)$.
For the case of $n \geq 3$, restrict $J'$ to be to the right of $J$, and let $t_n = x_J + x_{J'}/2$, so that $|x_J - t_n|, |x_{J'} - t_n| \simeq n|J|$. First, estimate the integral in the definition of $M_s$ on the interval $[t_n, \infty)$:

$$\frac{w(J')}{|J'|} \int_{t_n}^{\infty} \frac{|J'|^2}{|J|^2 + |x - x_J|^2} \cdot \frac{|J'|}{|J'|^2 + |x - x_{J'}|^2} d\sigma \lesssim A_2 \frac{2^{-2s}}{n^2}.$$ 

Then estimate the sum over $J'$ as follows:

$$\sum_{F' \in \mathcal{F}} \sum_{J' \in \mathcal{F}^e(F') : |J'|=2^{-s}|J|} \sum_{(n-1)|J| \leq \text{dist}(J,J') \leq n|J|} \frac{2^{-2s}}{n^2} \lesssim \frac{2^{-s}}{n^2}.$$ 

This is clearly summable in $n \geq 4$.

Now, estimate on the integral on the interval $(-\infty, t_n)$:

$$\frac{w(J')}{|J'|} \int_{-\infty}^{t_n} \frac{|J'|^2}{|J|^2 + |x - x_J|^2} \cdot \frac{|J'|}{|J'|^2 + |x - x_{J'}|^2} d\sigma$$

$$= 2^{-2s} \frac{w(J')}{|J|} \int_{-\infty}^{t_n} \frac{|J|}{|J|^2 + |x - x_J|^2} \cdot \frac{|J|^2}{|J'|^2 + |x - x_{J'}|^2} d\sigma$$

$$\lesssim 2^{-2s} \frac{w(J')}{n^2|J|} P(\sigma, J).$$

Drop the term with the geometric decay in $s$, and sum over $n$ and $J'$ to see that

$$\sum_{n=4}^{\infty} \sum_{F' \in \mathcal{F}} \sum_{J' \in \mathcal{F}^e(F') : |J'|=2^{-s}|J|} \sum_{(n-1)|J| \leq \text{dist}(J,J') \leq n|J|} \frac{w(J')}{n^2|J|} P(\sigma, I) \lesssim P(w, J) P(\sigma, J) \lesssim A_2.$$ 

Here, we have appealed to the full Poisson $A_2$ condition. This completes the control of the dual Poisson testing condition.

**Acknowledgments.** The authors benefited from a stimulating conference on two-weight inequalities in October 2011 at the American Institute of Mathematics in Palo Alto, California, for which they express their appreciation. The reviewing process led to many improvements in this paper, including a streamlining of the main contribution, for which we thank the referees.
